

# Package ‘Ecfun’

June 15, 2022

**Version** 0.2-6

**Date** 2022-06-13

**Title** Functions for 'Ecdat'

**Author** Spencer Graves <spencer.graves@effectivedefense.org>

**Maintainer** Spencer Graves <spencer.graves@effectivedefense.org>

**Depends** R (>= 3.5.0)

**Suggests** car, DescTools, Ecdat, maps, grid, gridBase, pryr, knitr, rmarkdown, invgamma, ipumsr, lubridate, bayesplot, bssm, ggplot2, tibble, kableExtra, openxlsx, fitdistrplus, purrr, markdown, EnvStats, drc, zoo, proclim, plyr, TRAMPR, raster, readxl

**VignetteBuilder** knitr

**Imports** fda, tis, jpeg, MASS, TeachingDemos, stringi, methods, xml2, BMA, mvtnorm, rvest

**Description** Functions and vignettes to update data sets in 'Ecdat' and to create, manipulate, plot, and analyze those and similar data sets.

**License** GPL (>= 2)

**Language** en-us

**URL** <https://www.r-project.org>

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2022-06-15 08:30:19 UTC

Arrows	<i>Draw arrows between pairs of points.</i>
--------	---

---

### Description

Generalizes `graphics::arrows` to allow all arguments to be vectors. (As of R 3.1.0, only the first component of the `length` argument is used by `graphics::arrows`; others are ignored without a warning.)

### Usage

```
Arrows(x0, y0, x1 = x0, y1 = y0, length = 0.25, angle = 30,
       code = 2, col = par("fg"), lty = par("lty"),
       lwd = par("lwd"), warnZeroLength=FALSE, ...)
```

### Arguments

`x0`, `y0`, `x1`, `y1`, `length`, `angle`, `code`, `col`, `lty`, `lwd`, ...  
as for [arrows](#).

`warnZeroLength` Issue a warning for zero length arrow? [arrow](#) does; skip if `FALSE`.

### Details

1. Put all arguments in a `data.frame` to force them to shared length.
2. Call [arrows](#) once for each row.

### Author(s)

Spencer Graves

[arrows](#)

## Examples

```
##  
## 1. Simple example:  
##   3 arrows, the first with length 0 is suppressed  
##  
plot(1:3, type='n')  
Arrows(1, 1, c(1, 2, 2), c(1, 2:3), col=1:3, length=c(1, .2, .6))  
  
##  
## 2. with an NA  
##  
plot(1:3, type='n')  
Arrows(1, 1, c(1, 2, 2), c(1, 2, NA), col=1:3, length=c(1, .2, .6))
```

---

as.Date1970

*Date from a number of days since the start of 1970.*

---

## Description

as.Date.numeric requires origin to be specified. The present function assumes that this origin is January 1, 1970.

## Usage

```
as.Date1970(x, ...)
```

## Arguments

x                    a numeric vector of dates in days since the start of 1970.  
...                  optional arguments to pass to as.Date.

## Value

Returns a vector of Dates

## Author(s)

Spencer Graves

## See Also

[as.Date](#) [as.POSIXct1970](#)

**Examples**

```

days <- c(0, 1, 365)
Dates <- as.Date1970(days)

all.equal(c('1970-01-01', '1970-01-02', '1971-01-01'),
          as.character(Dates))

all.equal(days, as.numeric(Dates))

```

---

asNumericDF

*Coerce to numeric dropping commas and info after a blank*

---

**Description**

For `asNumericChar`, delete leading blanks and a leading dollar sign plus commas (thousand separators) and drop information after a blank (other than leading blanks), then coerce to numeric or to factors, Dates, or POSIXct as desired.

For a `data.frame`, apply `asNumericChar` to all columns and drop columns except those in `keep`, `ignore`, factors, Dates, POSIX and MSdates.

Then order the rows by the `orderBy` column. Some Excel imports include commas as thousand separators; this replaces any commas with `char(0)`, `"`, before trying to convert to numeric.

Similarly, if `"%"` is found as the last character in any field, drop the percent sign and divide the resulting numeric conversion by 100 to convert to proportion.

Also, some character data includes footnote references following the year.

For example Table F-1 from the US Census Bureau needs all three of these numeric conversion features: It needs `orderBy`, because the most recent year appears first, just the opposite of most other data sets where the most recent year appears last. It has footnote references following a character string indicating the year. And it includes commas as thousand separators.

**Usage**

```

asNumericChar(x, leadingChar='^\\$',
              suppressChar=',', pctChar='%$',
              class=NULL, format=NULL)
asNumericDF(x, keep=
            function(x)any(!is.na(x)),
            orderBy=NA, ignore=NULL, factors=NULL,
            Dates=NULL, POSIX=NULL, MSdates=NULL,
            format=NULL, leadingChar='^\\$',
            suppressChar=',', pctChar='%$')

```

**Arguments**

x	For asNumericChar, this is a character vector to be converted to numeric after <code>gsub(',', '', x)</code> . For asNumericDF, this is a <code>data.frame</code> with all character columns to be converted to numerics.
keep	something to indicate which columns to keep, in addition to columns specified in <code>ignore</code> , <code>factors</code> , <code>Dates</code> , and <code>POSIX</code> .
orderBy	Which columns to order the rows of <code>x[, keep]</code> by. Default is to keep the input order.
ignore	vector identifying columns of <code>x</code> to ignore, i.e., to keep and not attempt to convert to another data type.
factors	vector indicating columns of <code>x</code> to convert to <code>factor</code>
Dates	vector indicating columns of <code>x</code> to convert using <code>as.Date(, format)</code> .
POSIX	vector indicating columns of <code>x</code> to convert using <code>as.POSIXct(, format)</code> .
class.	Desired class of output. Default is <code>numeric</code> .
format.	Character vector of length 1 to pass as argument <code>format</code> to <code>as.Date</code> and / or <code>as.POSIXct</code> for conversion from <code>character</code> . For Dates, <code>as.Date</code> is first tried with <code>format = '%Y-%m-%d'</code> , then with <code>'%Y/%m/%d'</code> , <code>'%m-%d-%Y'</code> , and <code>'%m/%d/%Y'</code> . The conversion with the fewest NAs is kept. If two match for numbers of NAs, the one with the minimum absolute deviations from <code>as.Date1970(0)</code> is used.
MSdates	The names or numbers identifying columns of <code>x</code> identifying dates as integer numbers of days since 1899-12-31. <b>In Microsoft Excel, dates are stored in that format.</b>
leadingChar	A regular expression passed to <code>grep</code> and <code>sub</code> to replace something like an initial dollar sign with character <code>(0)</code> .
suppressChar	a regular expression passed to <code>gsub</code> to replace all occurrences of something like <code>","</code> (a thousands separator in the U.S.) with character <code>(0)</code> .
pctChar	A regular expression passed to <code>grep</code> to identify percent columns. <code>pctChar</code> is then passed to <code>sub</code> to replace <code>pctChar</code> with character <code>(0)</code> , and the converted numbers are then divided by 100 to convert them to proportions.

**Details**

For `asNumericChar`:

1. Replace commas by nothing
2. `strsplit` on `' '` and take only the first part, thereby eliminating the footnote references.
3. Replace any blanks with NAs
4. `as.numeric`

for `asNumericDF`:

1. Copy `x` to `X`.

2. Confirm that ignore, factors, Dates, and POSIX all refer to columns of x and do not overlap. [\*\*\* NOTE: as of 2016-07-21, these checks have only been implemented for ignore.]
3. Convert factors, Dates, and POSIX.
4. Apply asNumericChar to all columns not in ignore, factors, Dates, or POSIX.
5. Keep columns specified by keep.
6. return the result.

## Value

a `data.frame`

  all.equal(nF1, nF1t)
}
```

---

BoxCox

*Box-Cox power transformation and its inverse*

---

## Description

Box and Cox (1964) considered the following family of transformations indexed by  $\lambda$ :

$$w = (y^{\lambda} - 1) / \lambda$$

$$= \expm1(\lambda \log(y)) / \lambda,$$

with the  $\lambda = 0$  case defined as  $\log(y)$  to make  $w$  continuous in  $\lambda$  for constant  $y$ .

They estimate  $\lambda$  assuming  $w$  follows a normal distribution. This raises a theoretical problem in that  $y$  must be positive, which means that  $w$  must follow a truncated normal distribution conditioned on  $\lambda w > (-1)$ .

Bickel and Doksum (1981) removed the restriction to positive  $y$ , i.e., to  $w > (-1/\lambda)$  by modifying the transformation as follows:

$w =$

$$(\text{sgn}(y) * \text{abs}(y)^{\lambda} - 1) / \lambda \text{ if } \lambda \neq 0 \text{ and}$$

$$\text{sgn}(y) * \log(\text{abs}(y)) \text{ if } \lambda = 0,$$

where  $\text{sgn}(y) = 1$  if  $y \geq 0$  and  $-1$  otherwise.

NOTE:  $\text{sgn}(y)$  is different from  $\text{sign}(y)$ , which is 0 for  $y = 0$ . A two-argument update to the  $\text{sign}$  function in the base package has been added to this Ecfun package, so  $\text{sign}(y, 1) = \text{sgn}(y)$ .

If  $(y < 0)$ , this transformation is discontinuous at  $\lambda = 0$ . To see this, we rewrite this as

$$w = (\text{sgn}(y) * \expm1(\lambda \log(\text{abs}(y))) + (\text{sgn}(y) - 1)) / \lambda$$

$$= \text{sgn}(y) * (\log(\text{abs}(y)) + 0(\lambda)) + (\text{sgn}(y) - 1) / \lambda,$$

where  $O(\lambda)$  indicates a term that is dominated by a constant times  $\lambda$ .

If  $y < 0$ , this latter term  $(\text{sgn}(y)-1)/\lambda = (-2)/\lambda$  and becomes  $\text{Inf}$  as  $\lambda \rightarrow 0$ .

In practice, we assume that  $y > 0$ , so this distinction has little practical value. However, the BoxCox function computes the Bickel-Doksum version.

Box and Cox further noted that proper estimation of  $\lambda$  should include the Jacobian of the transformation in the  $\log(\text{likelihood})$ . Doing this can be achieved by rescaling the transformation with the  $n$ th root of the Jacobian, which can be written as follows:

$$j(y, \lambda) = J(y, \lambda)^{1/n} = \text{GeometricMean}(y)^{(\lambda-1)}.$$

With this the rescaled power transformation is as follows:

$$z = (y^{\lambda-1}) / (\lambda * j(y, \lambda)) \text{ if } \lambda \neq 0 \text{ or } \text{GeometricMean}(y) * \log(y) \text{ if } \lambda == 0.$$

In addition to facilitating estimation of  $\lambda$ , rescaling has the advantage that the units of  $z$  are the same as the units of  $y$ .

The output has class `BoxCox`, which has attributes that allow the input to be recovered using `invBoxCox`. The default values of the arguments of `invBoxCox` are provided by the corresponding [attributes](#) of  $z$ .

### Usage

```
BoxCox(y, lambda, rescale=TRUE, na.rm=rescale)
invBoxCox(z, lambda, sign.y, GeometricMean, rescale)
```

### Arguments

<code>y</code>	a numeric vector for which the power transform is desired
<code>lambda</code>	A numeric vector of length 1 or 2. The first component is the power. If the second component is provided, $y$ is replaced by $y + \text{lambda}[2]$ .
<code>rescale</code>	logical or numeric. If logical: For <code>BoxCox</code> , this is <code>TRUE</code> to return the power transform with rescale, $z$ , above, and <code>FALSE</code> to return the power transform without the $n$ th root of the Jacobian, $w$ , above. This defaults to <code>TRUE</code> , because this will give $z$ the same units as $y$ . For <code>invBoxCox</code> , this is <code>TRUE</code> if the input argument $z$ is assumed to have been rescaled by the $n$ th root of the Jacobian of the transformation. This defaults to a <code>rescale</code> attribute of $z$ if present or to <code>TRUE</code> if absent. If numeric, it is assumed to be the geometric mean of another set of $y$ values to use with new $y$ 's.
<code>na.rm</code>	logical: <code>TRUE</code> to remove NAs from $y$ before computing the geometric mean. <code>FALSE</code> to compute NA for the geometric mean if <code>any(is.na(y))</code> . NOTE: If <code>na.rm = FALSE</code> , the output will be all NA if <code>rescale = TRUE</code> . This could produce non usable answers in most cases. To avoid that, the default for <code>na.rm</code> is <code>TRUE</code> whenever <code>rescale = TRUE</code> . Conversely, applications using <code>na.rm = FALSE</code> will likely also want <code>rescale = FALSE</code> to avoid returning a non-answer in these cases. This explains the default <code>na.rm = rescale</code> .
<code>z</code>	a numeric vector or an object of class <code>BoxCox</code> for which the inverse Box-Cox transform is desired.

- `sign.y` an optional logical vector giving `sign(y-lambda[2])` of the data values that presumably generated `z`. Defaults to a `sign.y` attribute of `z` or to `rep(1, length(z))` if no such attribute is present.
- `GeometricMean` an optional numeric scalar giving the geometric mean of the data values that presumably generated `z`. Defaults to a `GeometricMean` attribute of `z` or to 1 if no such attribute is present.

## Details

Box and Cox (1964) discussed

$$w(y, \lambda) = (y^\lambda - 1)/\lambda.$$

They noted that  $w$  is continuous in  $\lambda$  with  $w(y, \lambda) = \log(y)$  if  $\lambda = 0$  (by l'Hopital's rule).

They also discussed

$$z(y, \lambda) = (y^\lambda - 1) / (\lambda * g^{(\lambda-1)}),$$

where  $g$  = the geometric mean of  $y$ .

They noted that proper estimation of  $\lambda$  should include the Jacobian of  $w(y, \lambda)$  with the likelihood. They further showed that a naive normal likelihood using  $z(y, \lambda)$  as the response without a Jacobian is equivalent to the normal likelihood using  $w(y, \lambda)$  adjusted appropriately using the Jacobian. See Box and Cox (1964) or [the Wikipedia article on "Power transform"](#).

Bickel and Doksum (1981) suggested adding  $\text{sign}(y)$  to the transformation, as discussed above.

NUMERICAL ANALYSIS:

Consider the Bickel and Doksum version described above:

$$w \leftarrow (\text{sign}(y) * \text{abs}(y)^\lambda - 1) / \lambda$$

`if(any(y==0)), GeometricMean(y) = 0`. This creates a problem with the above math.

Let  $ly = \log(\text{abs}(y))$ . Then with  $la = \lambda$ ,

$$w = (\text{sign}(y) * \exp(la * ly) - 1) / la$$

$$= \text{sign}(y) * ly * (1 + (la * ly / 2) * (1 + (la * ly / 3) * (1 + (la * ly / 4) * (1 + 0(la * ly)))))) + (\text{sign}(y) - 1) / la$$

For  $y > 0$ , the last term is zero. `boxcox` ignores cases with  $y \leq 0$  and uses this formula (ignoring the final  $0(la * ly)$ ) whenever  $\text{abs}(la) \leq \text{eps} = 1/50$ . That form is used here also.

For `invBoxCox` a complementary analysis is as follows:

$$\text{abs}(y + \lambda[2]) = \text{abs}(1 + la * w)^(1/la)$$

$$= \exp(\log1p(la * w) / la) \text{ for } \text{abs}(la * w) < 1$$

$$= w * (1 - la * w * ((1/2) - la * w * ((1/3) - la * w * (1/4 - \dots))))$$

## Value

`BoxCox` returns an object of class `BoxCox`, being a numeric vector of the same length as `y` with the following optional attributes:

- `lambda` the value of  $\lambda$  used in the transformation

- `sign.y` `sign(y)` (or `sign(y-lambda[2])` `lambda[2]` is provided and if any of these quantities are negative. Otherwise, this is omitted and all are assumed to be positive.
- `rescale` logical: TRUE if `z(y, lambda)` is returned rescaled by  $g^{(\lambda-1)}$  with  $g$  = the geometric mean of  $y$  and FALSE if `z(y, lambda)` is not so rescaled.
- `GeometricMean` If `rescale` is numeric, `attr(, 'GeometricMean') <- rescale`. Otherwise, `attr(, 'GeometricMean')` is the Geometric mean of  $\text{abs}(y) = \exp(\text{mean}(\log(\text{abs}(y))))$  or of  $\text{abs}(y+\text{lambda}[2])$  if  $(\text{length}(\text{lambda})>1)$ .

`invBoxCox` returns a numeric vector, reconstructing  $y$  from `BoxCox(y, ...)`.

camelParse	<i>Split a character string where a capital letter follows a lowercase letter</i>
------------	---

---

### Description

Split a character string where a capital letter follows a lowercase letter.

### Usage

```
camelParse(x, except=c('De', 'Mc', 'Mac'))
```

### Arguments

x	a character vector
except	character vector giving exceptions: If any of these are found, ignore and look for the next one

### Details

Find all places where a lowercase letter is followed by a capital.

Split on those points

### Value

list of character vectors

### Author(s)

Spencer Graves

### See Also

[strsplit](#)

**Examples**

```
tst <- c('Smith, JohnJohn Smith',
        'EducationNational DefenseOther Committee',
        'McCain, JohnJohn McCain')
tst. <- camelParse(tst)

all.equal(tst., list(c('Smith, John', 'John Smith'),
                    c('Education', 'National Defense', 'Other Committee'),
                    c('McCain, John', 'John McCain') ) )
```

---

canbeNumeric

*Can a variable reasonably be coerced to numeric?*

---

**Description**

Can [seq](#) be reasonably applied to *x*? Returns TRUE if yes and FALSE otherwise.

We'd like to use this with, for example, date-time objects in [as.Date](#) and [as.POSIXct](#) formats. However, [as.numeric](#) of such objects is FALSE. Moreover, [as.numeric](#) of [factors](#) is TRUE.

The current algorithm (which may change in the future) returns TRUE if (`mode(x) == 'numeric'`) & (!('levels' %in% names(attributes(x)))).

**Usage**

```
canbeNumeric(x)
```

**Arguments**

*x*                    an R object

**Value**

A [logical](#) as described above.

**Author(s)**

Spencer Graves

**See Also**

[mode](#)

**Examples**

```
##
## Examples adapted from "mode"
##
cex4 <- c('letters[1:4]', "as.Date('2014-01-02')",
  'factor(letters[1:4])', "NULL", "1", "1:1", "1i",
  "list(1)", "data.frame(x = 1)", "pairlist(pi)",
  "c", "lm", "formals(lm)[[1]]", "formals(lm)[[2]]",
  "y ~ x", "expression((1))[[1]]", "(y ~ x)[[1]]",
  "expression(x <- pi)[[1]][[1]]")
lex4 <- sapply(cex4, function(x) eval(parse(text = x)))
mex4 <- t(sapply(lex4, function(x)
  c(typeof(x), storage.mode(x), mode(x), canbeNumeric(x))))
dimnames(mex4) <- list(cex4,
  c("typeof(.)", "storage.mode(.)", "mode(.)", 'canbeNumeric(x)'))
mex4

# check
mex. <- as.character(as.logical(c(0, 1, 0, 0, 1, 1, rep(0, 12))))
names(mex.) <- cex4

all.equal(mex4[,4], mex.)
```

---

checkNames

*Check and return names*

---

**Description**

Check and return [names](#). If names are not provided or are not unique, write a message and return [make.names](#) consistent with [warn](#) and [unique](#).

**Usage**

```
checkNames(x, warn=0, unique=TRUE,
  avoid=character(0),
  message0=head(deparse(substitute(x), 25), 2), ...)
```

**Arguments**

x	an R object suitable for <a href="#">names</a>
warn	Numeric code for how to treat problems, consistent with the argument <a href="#">warn</a> in <a href="#">options</a> : Negative to ignore, 0 to save and print later, 1 to print as they occur, 2 or greater to convert to errors.
unique	logical: TRUE to check that <code>names(x)</code> are unique. Fix any duplicates with <a href="#">make.names</a> .

`avoid` a vector of regular expressions to avoid adding in the output of `make.names` with a companion replacement when found.  
Thus, `length(avoid)` must be a nonnegative even integer, with `avoid[2*j-1]` providing the pattern for `regexpr` and `sub`, and `avoid[2*j]` providing the replacement. See the second example.

`message0` Base to prepend to any message

... optional arguments for `make.names`

### Details

1. `namex <- names(x)`
2. Check per `warn` and `unique`
3. Return an appropriate version of `namex`

### Value

a character vector of the same length as `x`. If any problem is found, this character vector will have an attribute `message` describing the problem found. Message checking considers `unique` but ignores `warn`.

### Author(s)

Spencer Graves

### See Also

[names](#) [make.names](#) [options](#) for `warn`

### Examples

```
##
## 1. standard operation with no names
##
tst1 <- checkNames(1:2)

# check
tst1. <- make.names(character(2), unique=TRUE)
attr(tst1., 'message') <- paste(
  "1:2: names = NULL; returning",
  "make.names(character(length(x))), TRUE)")

all.equal(tst1, tst1.)

##
## 2. avoid=c('\\.0$', '\\.1$')
##
tst2 <- checkNames(1:2,
  avoid=c('\\.0$', '.2',
    '\\.1$', '.3') )
```

```
# check
tst2. <-c('X', 'X.3')
attr(tst2., 'message') <- paste(
  "1:2: names = NULL; returning",
  "make.names(character(length(x))), TRUE)")

all.equal(tst2, tst2.)
```

---

classIndex

*Convert class to an integer 1-8 and vice versa*

---

## Description

classIndex converts the class of x to an integer:

1. NULL
2. logical
3. integer
4. numeric
5. complex
6. raw
7. character
8. other

index2class converts an integer back to the corresponding class.

## Usage

```
classIndex(x)
index2class(i, otherCharacter=TRUE)
```

## Arguments

x                    an object whose class index is desired.

i                    an integer to be converted to the name of the corresponding class

otherCharacter    logical: TRUE to convert 8 to "character"; FALSE to convert 8 to "other".

## Details

The [Writing R Extensions](#) lists six different kinds of "atomic vectors": logical, integer, numeric, complex, character, and raw: See also [Wickham \(2013, section on "Atomic vectors" in the chapter on "Data structures"\)](#). These form a standard hierarchy, except for "raw", in that standard operations combining objects with different atomic classes will create an object of the higher class. For example, `TRUE + 2 + pi` returns a numeric object ((approximately 6.141593). Similarly, `paste(1, 'a')` returns the character string "1 a".

For "interpolation", we might expect users interpolating between objects of class "raw" (i.e., bytes) might most likely prefer "Numeric" to "Character" interpolation, coerced back to type "raw".

The index numbers for the classes run from 1 to 8 to make it easy to convert them back from integers to character strings.

## Value

`classIndex` returns an integer between 1 and 7 depending on `class(x)`.

`index2class` returns a character string for the inverse transformation.

## Author(s)

Spencer Graves

## References

Wickham, Hadley (2014) *Advanced R*, especially [Wickham \(2013, section on "Atomic vectors" in the chapter on "Data structures"\)](#).

## Examples

```
##
## 1. classIndex
##
x1 <- classIndex(NULL)
x2 <- classIndex(logical(0))
x3 <- classIndex(integer(1))
x4 <- classIndex(numeric(2))
x5 <- classIndex(complex(3))
x6 <- classIndex(raw(4))
x7 <- classIndex(character(5))
x8 <- classIndex(list())

# check

all.equal(c(x1, x2, x3, x4, x5, x6, x7, x8), 1:8)

##
```

```
## 2. index2class
##
c1 <- index2class(1)
c2 <- index2class(2)
c3 <- index2class(3)
c4 <- index2class(4)
c5 <- index2class(5)
c6 <- index2class(6)
c7 <- index2class(7)
c8 <- index2class(8)
c8o <- index2class(8, FALSE)

# check

all.equal(c(c1, c2, c3, c4, c5, c6, c7, c8, c8o),
          c('NULL', 'logical', 'integer', 'numeric',
            'complex', 'raw', 'character', 'character',
            'other'))
```

---

compareLengths

*Compare the lengths of two objects*

---

## Description

Issue a warning or error if the lengths of two objects are not compatible.

## Usage

```
compareLengths(x, y,
               name.x=deparse(substitute(x), width.cutoff,
                               nlines=1, ...),
               name.y=deparse(substitute(y), width.cutoff,
                               nlines=1, ...),
               message0='', compFun=c('NROW', 'length'),
               action=c(compatible='', incompatible='warning'),
               length0=c('compatible', 'incompatible', 'stop'),
               width.cutoff=20, ...)
```

## Arguments

<code>x, y</code>	objects whose lengths are to be compared
<code>name.x, name.y</code>	names of <code>x</code> and <code>y</code> to use in a message. Default = <code>deparse(substitute(.), width.cutoff, nlines=1)</code> .
<code>message0</code>	character string to be included with <code>name.x</code> and <code>name.y</code> in a message.
<code>compFun</code>	function to use in the comparison.

action	A character vector of length 2 giving the names of functions to call if the lengths are not equal but are either 'compatible' or 'incompatible'; "" means no action.
length0	If length(x) or length(y) = 0 (but not both), treat this case as specified by length0.
width.cutoff	width.cutoff argument to pass to <a href="#">deparse</a> . This gives the maximum number of characters to use in a name in error and warning messages.
...	optional arguments for <a href="#">deparse</a>

### Details

1. If `nchar(name.x) = 0 = nchar(name.y)`, set `name.x <- 'x'`, `name.y <- 'y'`, and append 'in compareLengths:' to `message0` for more informative messaging.
2. `lenx <- do.call(compFun, list(x)); leny <- do.call(compFun, list(y))`
3. `if(lenx==leny)return(c('equal', ''))`
4. Compatible?
5. Compose the message.
6. "action", as indicated

### Value

A character vector of length 2. The first element is either 'equal', 'compatible' or 'incompatible'. The second element is the message composed.

### Author(s)

Spencer Graves with help from Duncan Murdoch

### Examples

```
##
## 1. equal
##

all.equal(compareLengths(1:3, 4:6), c("equal", ''))

##
## 2. compatible
##
a <- 1:2
b <- letters[1:6]
comp.ab <- compareLengths(a, b, message0='Chk:')
comp.ba <- compareLengths(b, a, message0='Chk:')
# check
```

```

chk.ab <- c('compatible',
           'Chk: length(b) = 6 is 3 times length(a) = 2')

all.equal(comp.ab, chk.ab)

all.equal(comp.ba, chk.ab)

##
## 3. incompatible
##
Z <- LETTERS[1:3]
comp.aZ <- compareLengths(a, Z)
# check
chk.aZ <- c('incompatible',
           ' length(Z) = 3 is not a multiple of length(a) = 2')

all.equal(comp.aZ, chk.aZ)

##
## 4. problems with name.x and name.y
##
comp.ab2 <- compareLengths(a, b, '', '')
# check
chk.ab2 <- c('compatible',
           'in compareLengths: length(y) = 6 is 3 times length(x) = 2')

all.equal(comp.ab2, chk.ab2)

##
## 5. zeroLength
##
zeroLen <- compareLengths(logical(0), 1)
# check
zeroL <- c('compatible', ' length(logical(0)) = 0')

all.equal(zeroLen, zeroL)

```

---

compareOverlap

*Compare y between newDat and refDat for shared values of x*

---

### Description

Compute  $dy <- (y - yRef)$  for all cases where  $x == xRef$ , where  $x$  and  $y$  are columns of `newDat` and `xRef` and `yRef` are columns of `refDat`.

Also compute  $dyRef <- dy / yRef$ .

Return silently a data.frame with columns `x`, `y`, `yRef`, `dy`, and `dyRef`.

Also if  $\min(yRef) * \max(yRef) > 0$  plot(`dyRef`) else plot(`dy`).

**Usage**

```
compareOverlap(y=2, yRef=y, x=1,
              xRef=x, newDat, refDat,
              ignoreCase=TRUE, ...)
```

**Arguments**

<code>y, yRef</code>	columns of <code>newDat</code> , <code>refDat</code> , respectively, to compare, ignoring case in the names unless <code>ignoreCase</code> is <code>FALSE</code> .
<code>x, xRef</code>	columns of <code>newDat</code> , <code>refDat</code> , respectively, to match when comparing <code>y</code> with <code>yRef</code> . As with <code>y</code> and <code>yRef</code> , ignore case in name matching unless <code>ignoreCase</code> is <code>FALSE</code> .
<code>newDat, refDat</code>	<code>data.frames</code> of new and reference data in which to search for overlap, i.e., common values of <code>newDat[, x]</code> and <code>refDat[, xRef]</code> , and for those observations to compare <code>newDat[, y]</code> to <code>refDat[, yRef]</code> .
<code>ignoreCase</code>	logical: If <code>TRUE</code> , ignore case when searching for columns of <code>newDat</code> and <code>refDat</code> to match <code>y</code> , <code>yRef</code> , <code>x</code> , and <code>xRef</code> .
<code>...</code>	optional arguments to pass to <code>plot</code>

**Details**

This function is particularly useful for updating datasets that are obtained from sources like the [Bureau of Justice Statistics](#), which publish many series with each update including the most recent 11 years. This function can be used to evaluate the extent of equivalence between, e.g., historical data in `refDat` with the latest data in `newDat`.

**Value**

Invisibly return a `data.frame` with columns `x`, `paste0(y, 'New')`, `paste0(yRef, 'Ref')`, `dy`, and `dyRef` of the data compared.

**Author(s)**

Spencer Graves

**Examples**

```
nDat <- data.frame(yr=2000:2015,
                  Y=0:15)
rDat <- data.frame(Yr=2018:2011,
                  y=c(17:13, 13:11))
nrDat <- compareOverlap(
  newDat=nDat, refDat=rDat)

# Correct answer
NRdat <- data.frame(yr=2011:2015,
                  YNew=11:15, yRef=c(11:13, 13:14),
                  dy=c(0,0,0, 1, 1),
                  dyRef=c(0,0,0, 1,1) /
```

```
c(11:13, 13:14))
```

```
all.equal(nrDat, NRdat)
```

---

confint.var

*Confidence interval for sample variance or standard deviation*

---

### Description

Computes the standard normal (i.e., chi-square) confidence intervals for a sample variance or standard deviation.

### Usage

```
## S3 method for class 'var'
confint(object, parm, level=0.95, ...)
## S3 method for class 'sd'
confint(object, parm, level=0.95, ...)
```

### Arguments

object	a numeric vector possibly with a <code>df</code> or <code>df.residuals</code> attribute assumed to represent a sample variance, possibly computed as root mean square of residuals from a model.
parm	degrees of freedom in the estimated variance or standard deviation.
level	the confidence level required
...	optional arguments not used.

### Details

1. If `object` is not numeric, throw an error.
2. If `parm` is missing, look for an attribute of `object` starting with `df`. If present, use that for `parm`. If `parm` is absent or not numeric, throw an error.
3. replicate `object`, `parm`, and `level` to the same length. Issue a warning if the longest is not a multiple of the others.
4. `alph2 <- (1-level)/2`
5. `Qntls <- cbind(lower=qchisq(alph2, parm, lower=FALSE), upper=qchisq(alph2, parm))`
6. `CI <- (object*parm/Qntls)`
7. `attr(CI, 'level') <- Level`
7. `return(CI)`

**Value**

a matrix with columns "lower" and "upper", nrow = the longest of the lengths of object, parm, and level, and an attribute "level".

```

---

countByYear

*Allocate a total by year*

---

### Description

Allocate total to countByYear for a constant count per day between start and end.

### Usage

```
countByYear(start, end, total=1)
```

### Arguments

start, end	objects of class "Date" specifying the start, end, respectively, of the event
total	A number to be allocated by year in proportion to the number of days in the event each year.

### Value

a numeric vector whose `sum` is total with names for all the years between start and end

### Author(s)

Spencer Graves

### Examples

```
##
## 1. All in one year
##
start73 <- as.Date('1973-01-22')
tst1 <- countByYear(start73, start73+99, 123)

# check
tst1. <- 123
names(tst1.) <- 1973

all.equal(tst1, tst1.)
```

```
##
## 2. Two years
##
tst2 <- countByYear(start73, start73+365, 123)

# check
dur <- 366
days1 <- (365-21)
days2 <- 22
tst2. <- 123 * c(days1, days2)/dur
names(tst2.) <- 1973:1974

all.equal(tst2, tst2.)

##
## 3. Ten years
##
tst10 <- countByYear(start73, start73+10*365.2, 123)

# check
days <- (c(rep(c(rep(365, 3), 366), length=10), 0)
          + c(-21, rep(0, 9), 22) )
tst10. <- 123 * days/(10*365.2+1)
names(tst10.) <- 1973:1983

all.equal(tst10, tst10.)
```

---

countsByYear

*Allocate totals by year*

---

### Description

Allocate total to countByYear for a constant count per day between start and end for multiple events.

### Usage

```
countsByYear(data, start="Start1", end='End1',
             total='BatDeath', event='WarName',
             endNA=max(data[, c(start,end)]))
```

### Arguments

data            a [data.frame](#) with columns start, end, and total

start, end	columns of data of class Date with start <= end during which total is to be allocated
total	A quantity to be allocated by year giving a constant rate per day.
event	name of the event whose total is to be allocated.
endNA	Date to use if is.na(data[, end]).

**Value**

a numeric `matrix` whose `colSums` match `total` with names for all the years between `start` and `end`. The number of columns of the output matrix match the number of rows of data. The `colSums` match `total`.

**Author(s)**

Spencer Graves

**Examples**

```
##
## 1. data.frame(WarName, Start1, End1, BatDeath)
##
start73 <- as.Date('1973-01-22')
tstWars <- data.frame(WarName=c('short', '2yr', '10yr'),
  Start1=c(start73, start73+365, start73-365),
  End1=start73+c(99, 2*365, NA),
  BatDeath=c(100, 123, 456))
##
## 2. do
##
deathsByYr <- countsByYear(tstWars,
  endNA=start73+9*365.2)

# check
Counts <- matrix(0, 11, 3,
  dimnames=list(c(1972:1982), tstWars$WarName) )
Counts['1973', 1] <- 100
Counts[as.character(1974:1975), 2] <- with(tstWars,
  countByYear(Start1[2], End1[2], BatDeath[2]) )
Counts[as.character(1972:1982), 3] <- with(tstWars,
  countByYear(Start1[3], start73+9*365.2, BatDeath[3]) )

all.equal(deathsByYr, Counts)
```

---

createMessage	<i>Compose a message as a single substring from a character vector</i>
---------------	--

---

### Description

This is a utility function to make it easier to automatically compose informative error and warning messages without using too many characters.

### Usage

```
createMessage(x, width.cutoff=45, default='x',
             collapse='; ', endchars='...')
```

### Arguments

x	input for <a href="#">paste</a>
width.cutoff	maximum number of characters from x to return in a single string. This differs from the width.cutoff argument in <a href="#">deparse</a> in that the output included here considers endchars, not part of <a href="#">deparse</a> .
default	character string to return if nchar(x) = 0.
collapse	collapse argument for <a href="#">paste</a>
endchars	a character string to indicate that part of the input string(s) was truncated.

### Details

```
x. <- paste(..., collapse='; ') nchx <- nchar(x.) maxch <- (maxchar-nchar(endchars)) if(nchx>maxch){
x2 <- substring(x., 1, maxch) x. <- paste0(x2, endchar) }
```

### Value

a character string with at most width.cutoff characters.

### Author(s)

Spencer Graves

### See Also

[paste](#) [substr](#) [nchar](#)

**Examples**

```
##
## 1. typical use
##
tstVec <- c('Now', 'is', 'the', 'time')
msg <- createMessage(tstVec, 9, collapse=':',
                    endchars='//')

all.equal(msg, 'Now:is://')

##
## 2. in a function
##
tstFn <- function(cl)createMessage(deparse(cl), 9)
Cl <- quote(plot(1:3, y=4:6, col='red', main='Title'))
msg0 <- tstFn(Cl)
# check
msg. <- 'plot(1...)'

all.equal(msg0, msg.)

##
## 3. default
##
y <- createMessage(character(3), default='y')

all.equal(y, 'y')
```

---

createX2matchY

*Create X to match Y*

---

**Description**

Return a default object of class `index2class(max(classIndex(x), classIndex(y)))` and `length = length(y)`.

For example, suppose `class(x) == 'numeric'`, for which `classIndex = 4`. If `class(y) = 'integer'`, then an object of class `'numeric'` is returned. However, if `class(y) = 'character'`, then an object of class `'character'` is returned.

**Usage**

```
createX2matchY(x, y)
```

**Arguments**

`x, y` objects of possibly different classes and lengths.

**Value**

A vector of the same length as `y` whose class is `index2class(max(classIndex(x), classIndex(y)))`.

**Author(s)**

Spencer Graves

**See Also**

[interpPairs](#)

**Examples**

```
##

```

---

Date3to1	<i>Convert three YMD vectors to a Date</i>
----------	--

---

### Description

Given a `data.frame` with 3 columns, assume they represent Year, Month and Day and return a vector of class `Date`.

### Usage

```
Date3to1(data, default='Start')
```

### Arguments

`data` a `data.frame` with 3 columns assumed to represent Year, Month and Day.

`default` A character string to indicate how missing months and days should be treated. If the first letter is "S" or "s", the default month will be 1 and the default day will be 1. Otherwise, "End" is assumed, for which the default month will be 12 and the default day will be the last day of the month.

NOTE: Any number outside the range of 1 to the last day of the month is considered missing and its subscript is noted in the optional attribute "missing".

### Details

The data sets from the [Correlates of War](#) project include dates coded in triples of columns with names like

```
c("StartMonth1", "StartDay1", "StartYear1", "EndMonth1", ..., "EndYear2").
```

This function will accept one triple and translate it into a vector of class `Date`.

### Value

Returns an object of class `Date` with an optional attribute `missing` giving the indices of any elements with missing months or days, for which a default month or day was supplied.

dateCols	<i>Identify YMD names in a character vector</i>
----------	---

---

**Description**

`grep` for YMD (year, month, day) in `col.names`. Return a named list of integer vectors of length 3 for each triple found.

**Usage**

```
dateCols(col.names, YMD=c('Year', 'Month', 'Day'))
```

**Arguments**

<code>col.names</code>	either a character vector in which to search for names matching YMD or an object with non-null <code>colnames</code>
<code>YMD</code>	a character vector of patterns to use in <code>grep</code> to identify triples of columns coding YMD in <code>col.names</code>

## Details

The data sets from the [Correlates of War](#) project include dates coded in triples of columns with names like `c("StartMonth1", "StartDay1", "StartYear1", "EndMonth1", ..., "EndYear2")`. This function will find all relevant date triples in a character vector of column names and return a list of integer vectors of length 3 with names like `"Start1", "End1", ..., "End2"` giving the positions in `col.names` of the desired date components.

Algorithm:

1. `if(!is.null(colnames(YMD)))YMD <- colnames(YMD)`
2. `ymd <- grep` for YMD (Year, Month, Day) in `col.names`.
3. `groupNames <- sub` pattern with `"` in `ymd`
4. Throw a [warning](#) for any `groupNames` character string that does not appear with all three of Year, Month, and Day.
5. Return a list of integer vectors of length 3 for each triple found.

## Value

Returns a named list of integer vectors of length 3 identifying the positions in `col.names` of the desired date components.

## Author(s)

Spencer Graves

```

---

Dates3to1

---

*Convert 3-column dates in data to class Date*

---

### Description

Return a `data.frame` with columns of class "Date" replacing all 3-column dates.

### Usage

```
Dates3to1(data, YMD=c('Year', 'Month', 'Day'))
```

### Arguments

<code>data</code>	a <code>data.frame</code> assumed to include dates coded in three column sets with names matching YMD.
<code>YMD</code>	a character vector of length 3 of patterns to use in <code>grep</code> to identify triples of columns coding YMD in <code>col.names(data)</code> .

### Details

The data sets from the **Correlates of War** project include dates coded in triples of columns with names like `c("StartMonth1", "StartDay1", "StartYear1", "EndMonth1", ..., "EndYear2")`. This function will accept a `data.frame` obtained via `read.csv` of such a file and replace each such triple with a single column of class 'Date' combining the triple appropriately.

### Value

Return a `data.frame` containing the information in data reformatted as described above.

### Author(s)

Spencer Graves

all.equal(cow0., cow0x)

```

---

deletedFunctions

*Functions deleted from the Ecfun package*

---

**Description**

Several functions were deleted from Ecfun 0.2-5, because they no longer worked, and it was not clear if there was demand for them.

If you need them, you can get the documentation and code for them from CRAN > Packages > Archive (near the bottom center) > Ecfun > Ecfun\_0.2-0.tar.gz. I don't expect the code to work. However, I might be willing to collaborate in restoring the functionality to Ecfun.

readFinancialCrisisFiles was a companion to a book. This function required the gdata package, which was scheduled to be removed from CRAN.

USsenateClass called by default readUSsenate. UShouse.senate and mergeUShouse.senate called by default both readUSsenate and readUShouse. The latter two and the remaining functions deleted did web scraping, and the web sites from which they scraped information changed, and it did not seem worth the work required to continue to maintain them.

---

getElement2

*Extract a named element from an object with a default*

---

**Description**

Get element name of object. If object does not have an element name, return default.

If the name element of object is NULL the result depends on warn.NULL: If TRUE, issue a warning and return default. Otherwise, return NULL

**Usage**

```

getElement2(object, name=1, default=NA,
  warn.NULL=TRUE, envir=list(), returnName)

```

**Arguments**

object	object from which to extract component name.
name	Name or index of the element to extract
default	default value if name is not part of object.
warn.NULL	logical to decide how to treat cases where object has a component name: If TRUE, return default with a warning. Otherwise, return NULL.
envir	Supplemental list beyond object in which to look for names in case object[[name]] is a language object that must be evaluated.
returnName	logical: TRUE to return <code>as.character</code> of any <code>name</code> found as an element of object. FALSE to <code>eval</code> any <code>name</code> found in the environment of object. Default = TRUE if name == 1 or a character string matching the name of the first element of object.

**Details**

1. If `is.numeric(name)` `In <- (1 <= name <= length(object))`
2. else `In <- if(name %in% names(object))`
3. `E1 <- if(In) object[[name]] else default`
4. `warn.NULL?`
5. `if(returnName) return(as.character(E1)) else return(eval(E1, envir=object))`

**Value**

an object of the form of `object[[name]]`; if object does not have an element or slot name, return default.

**Author(s)**

Spencer Graves with help from Marc Schwartz and Hadley Wickham

**See Also**

[getElement](#), which also can return slots from S4 objects.

**Examples**

# check

  all.equal(fn, 'plot')

  all.equal(eQuote, 1:4)
```

```

    all.equal(Col2, 2)
  }

```

---

```

grepNonStandardCharacters
      grep for nonstandard characters

```

---

### Description

Return the indices of elements of `x` containing characters that are not in `standardCharacters`.

### Usage

```

grepNonStandardCharacters(x, value=FALSE,
  standardCharacters=c(letters, LETTERS, ' ',
    '.', ',', '0:9', '\\\"', "\\'", '-_', '(',
    ')', '[', ']', '\\n'),
  ... )

```

### Arguments

<code>x</code>	character vector in which it is desired to identify elements containing characters not in <code>standardCharacters</code> .
<code>value</code>	logical: TRUE to return the values found in <code>x</code> , FALSE to return their indices.
<code>standardCharacters</code>	Characters to overlook in <code>x</code> to identify anything not in <code>standardCharacters</code> .
<code>...</code>	optional arguments for <a href="#">regexpr</a>

### Details

1. `x. <- strsplit(x, '')`: convert the input character vector to a list of vectors of character vectors with `nchar(x.[i]) == 1` for `i` in `1:length(x)`.
2. `sapply(x., ...)` to identify all elements for which any element of `x[[i]]` is not in `standardCharacters`.

### Value

an integer vector identifying all elements of `x` containing a character not in `standardCharacters`.

### Author(s)

Spencer Graves

all.equal(chk, 2)

chkv <- grepNonStandardCharacters(Names, TRUE)

all.equal(chkv, Names[2])

```

---

Interp

*Interpolate between numbers or numbers of characters*

---

**Description**

Numeric interpolation is defined in the usual way:

```
xOut <- x*(1-proportion) + y*proportion
```

Character interpolation does linear interpolation on the number of characters of `x` and `y`. If `length(proportion) == 1`, interpolation is done on `cumsum(nchar(.))`. If `length(proportion) > 1`, interpolation is based on `nchar`. In either case, the interpolant is rounded to an integer number of characters. `Interp` then returns `substring(y, ...)` unless `nchar(x) > nchar(y)`, when it returns `substring(x, ...)`.

Character interpolation is used in two cases: (1) At least one of `x` and `y` is character. (2) At least one of `x` and `y` is neither logical, integer, numeric, complex nor raw, and `class(unclass(.))` is either integer or character.

In all other cases, numeric interpolation is used.

NOTE: This seems to provide a relatively simple default for what most people would want from the six classes of atomic vectors (logical, integer, numeric, complex, raw, and character) and most other classes. For example, `class(unclass(factor))` is integer. The second rule would apply to this converting it to character. The `coredata` of an object of class `zoo` could be most anything, but this relatively simple rule would deliver what most people want in most case. An exception would be an object with integer `coredata`. To handle this as numeric, a `Interp.zoo` function would have to be written.

**Usage**

```

Interp(x, ...)
## Default S3 method:
Interp(x, y, proportion,

```

```

      argnames=character(3),
      message0=character(0), ...)
InterpChkArgs(x, y, proportion,
      argnames=character(3),
      message0=character(0), ...)
InterpChar(argsChk, ...)
InterpNum(argsChk, ...)

```

## Arguments

<code>x, y</code>	two vectors of the same class or to be coerced to the same class.
<code>proportion</code>	A number or numeric vector assumed to be between 0 and 1.
<code>argnames</code>	a character vector of length 3 giving arguments name .x, name .y, and <code>proportion</code> to pass to <code>compareLengths</code> to improve the value of any diagnostic message in case lengths are not compatible.
<code>message0</code>	A character string to be passed with <code>argnames</code> to <code>compareLengths</code> to improve the value of any diagnostic message in case lengths are not compatible.
<code>argsChk</code>	a list as returned by <code>interpChkArgs</code>
<code>...</code>	optional arguments for <code>compareLengths</code>

## Details

Interp is an S3 generic function to allow users to easily modify the behavior to interpolate between special classes of objects.

Interp has two basic algorithms for "Numeric" and "Character" interpolation.

The computations begin by calling `InterpChkArgs` to dispose quickly of simple cases (e.g. `x` or `y` `missing` or `length 0` or if `proportion` is  $\leq 0$  or  $\geq 1$  or `missing`). It returns a list.

If the list contains a component named `xout`, Interp returns that value with no further computations.

Otherwise, the list returned by `InterpChkArgs` includes components "algorithm", "x", "y", "proportion", `pLength1` (defined below), "raw", and "outclass". The "algorithm" component must be either "Numeric" or "Character". That algorithm is then performed as discussed below using arguments "x", "y", and "proportion"; all three will have the same length. The class of "x" and "y" will match the algorithm. The list component "raw" is logical: TRUE if the output will be raw or such that `class(unclass(.))` of the output will be raw. In that case, a "Numeric" interpolation will be transformed back into "raw". "outclass" will either be a list of attributes to apply to the output or NA. If a list, `xout` will be added as component ".Data" to the list "outclass" and then then processed as `do.call('structure', outclass)` to produce the desired output.

These two basic algorithms ("Numeric" and "Character") are the same if `proportion` is missing or not numeric: In that case Interp throws an error.

We now consider "Character" first, because it's domain of applicability is easier to describe. The "Numeric" algorithm is used in all other cases

### 1. "CHARACTER"

\* 1.1. The "CHARACTER" algorithm is used when at least one of `x` and `y` is neither logical, integer, numeric, complex nor raw and satisfies one of the following two additional conditions:

```

** 1.1.1. Either x or y is character.
** 1.1.2. class(unclass(.)) for at least one of x and y is either character or integer.
NOTE: The strengths and weaknesses of 1.1.2 can be seen in considering factors and integer vectors
of class zoo: For both, class(unclass(.)) is integer. For factors, we want to use as.character(.).
For zoo objects with coredata of class integer, we would want to use numeric interpolation. This
is not allowed with the current code but could be easily implemented by writing Interp.zoo.
* 1.2. If either x or y is missing or has length 0, the one that is provided is returned unchanged.
* 1.3. Next determine the class of the output. This depends on whether neither, one or both of x and
y have one of the six classes of atomic vectors (logical, integer, numeric, complex, raw, character):
** 1.3.1. If both x and y have one of the six atomic classes and one is character, return a character
object.
** 1.3.2. If only one of x and y have an atomic class, return an object of the class of the other.
** 1.3.3. If neither of x nor y have a basic class, return an object with the class of y.
* 1.4. Set pLength1 <- (length(proportion) == 1):
** 1.4.1. If (pLength1) do the linear interpolation on cumsum(nchar(.)).
** 1.4.2. Else do the linear interpolation on nchar.
* 1.5. Next check x, y and proportion for comparable lengths: If all have length 0, return an object
of the appropriate class. Otherwise, call compareLengths(x, proportion), compareLengths(y,
proportion), and compareLengths(x, y).
* 1.6. Extend x, y, and proportion to the length of the longest using rep.
* 1.7. nchOut <- the number of characters to output using numeric interpolation and rounding the
result to integer.
* 1.8. Return substring(y, 1, nchOut) except when the number of characters from x exceed
those from y, in which case return substring(x, 1, nchOut). [NOTE: This meets the naive end
conditions that the number of characters matches that of x when proportion is 0 and matches that
of y when proportion is 1. This can be used to "erase" characters moving from one frame to the
next in a video. See the examples.
2. "NUMERIC"
* 2.1. Confirm that this does NOT satisfy the condition for the "Character" algorithm.
* 2.2. If either x or y is missing or has length 0, return the one provided.
* 2.3. Next determine the class of the output. As for "Character" described in section 1.3, this
depends on whether neither, one or both of x and y have a basic class other than character (logical,
integer, numeric, complex, raw):
** 2.3.1. If proportion <= 0, return x unchanged. If proportion >= 1, return y unchanged.
** 2.3.2. If neither x nor y has a basic class, return an object of class equal that of y.
** 2.3.3. If exactly one of x and y does not have a basic class, return an object of class determined
by class(unclass(.)) of the non-basic argument.
** 2.3.4. When interpolating between two objects of class raw, convert the interpolant back to class
raw. Do this even when 2.3.2 or 2.3.3 applies and class(unclass(.)) of both x and y are of class
raw.

```

\* 2.4. Next check `x`, `y` and proportion for comparable lengths: If all have length 0, return an object of the appropriate class. Otherwise, call `compareLengths(x, proportion)`, `compareLengths(y, proportion)`, and `compareLengths(x, y)`.

\* 2.5. Compute the desired interpolation and convert it to the required class per step 2.3 above.

### Value

Interp returns a vector whose class is described in "\* 1.3" and "\* 2.3" in "Details" above.

InterpChkArgs returns a list or throws an error as described in "Details" above.

### Author(s)

Spencer Graves

### References

The *Writing R Extensions* manual (available via `help.start()`) lists six different classes of atomic vectors: [logical](#), [integer](#), [numeric](#), [complex](#), [raw](#) and [character](#).              units="days"))<0.5
```

interpChar

*Interpolate between numbers or numbers of characters***Description**

For x and y logical, integer, numeric, Date or POSIX:

```
xOut <- x*(1-.proportion) + y*.proportion
```

Otherwise, coerce to character and return a [substring](#) of x or y with number of characters interpolating linearly between nchar(x) and nchar(y); see details.

\*\*\* NOTE: This function is currently in flux. The results may not match the documentation and may change in the future.

The current version does character interpolation on the cumulative number of characters with defaults with only one argument that may not be easy to understand and use. Proposed:

old: interpolate on number of characters in each string with the default for a missing argument being character(length(x)) [or character(length(y)) or numeric(length(x)) or ...]

2014-08-08: default with either x or y missing should be to set the other to the one we have, so interpChar becomes a no op – except that values with .proportion outside (validProportion = [0, 1] by default) should be dropped.

**Usage**

```
interpChar(x, ...)
## S3 method for class 'list'
interpChar(x, .proportion,
           argnames=character(3),
           message0=character(0), ...)
## Default S3 method:
interpChar(x, y, .proportion,
           argnames=character(3),
           message0=character(0), ...)
```

**Arguments**

x	either a vector or a list. If a list, pass the first two elements as the first two arguments of interpChar.default.
y	a vector
.proportion	A number or numeric vector assumed to be between 0 and 1.
argnames	a character vector of length 3 giving arguments name.x, name.y, and .proportion to pass to <a href="#">compareLengths</a> to improve the value of any diagnostic message in case lengths are not compatible.
message0	A character string to be passed with argnames to <a href="#">compareLengths</a> to improve the value of any diagnostic message in case lengths are not compatible.
...	optional arguments for <a href="#">compareLengths</a>

## Details

1. `x`, `y` and `.proportion` are first compared for compatible lengths using `compareLengths`. A warning is issued if the lengths are not compatible. They are then all extended to the same length using `rep`.
2. If `x` and `y` are both numeric, `interpChar` returns the standard linear interpolation (described above).
3. If `x`, `y`, and `.proportion` are all provided with at least one of `x` and `y` not being numeric or logical, the algorithm does linear interpolation on the difference in the number of characters between `x` and `y`. It returns characters from `y` except when `nchar(x) > nchar(y)`, in which case it returns characters from `x`. This meets the end conditions that the number of characters matches that of `x` when `.proportion` is 0 and matches that of `y` when `.proportion` is 1. This can be used to "erase" characters moving from one frame to the next in a video. See the examples.
4. If either `x` or `y` is missing, it is replaced by a default vector of the same type and length; for example, if `y` is missing and `x` is numeric, `y = numeric(length(x))`. (If the one supplied is not numeric or logical, it is coerced to character.)

## Value

A vector: Numeric if `x` and `y` are both numeric and character otherwise. The length = max length of `x`, `y`, and `.proportion`.

## Author(s)

Spencer Graves

[classIndex](#), which is called by `interpChar` to help decide the class of the interpolant.

## Examples

```
##
## 1. numerics
##
# 1.1. standard
xNum <- interpChar(1:3, 4:5, (0:3)/4)
# answer
xN. <- c(1, 2.75, 3.5, 4)

all.equal(xNum, xN.)

# 1.2. list of length 1 with a numeric vector:
# return that vector with a warning
xN1 <- interpChar(list(a.0=1:4), .5)
# answer
xN1. <- 1:4
```

```

all.equal(xN1, xN1.)

##
## 2. Single character vector
##
i.5 <- interpChar(list(c('a', 'bc', 'def')), .p=0.3)
# If cumulative characters:
#       0.3*(total 6 characters) = 1.8 characters
#
# However, the current code does something different,
# returning "a", "bc", "d" <- like using 1-.p?
# This is a problem with the defaults with a single
# argument; ignore this issue for now.
# 2014-06-04
i.5. <- c('a', 'b', '')

#all.equal(i.5, i.5.)

##
## 3. Reverse character example
##
i.5c <- interpChar(c('a', 'bc', 'def'), '', 0.3)
# check: 0.7*(total 6 characers) = 4.2 characters
i.5c. <- c('a', 'bc', 'd')

all.equal(i.5c, i.5c.)

# The same thing specified in a list
i.5d <- interpChar(list(c('a', 'bc', 'def'), ''), 0.3)

all.equal(i.5d, i.5c.)

##
## 4. More complicated example
##
xCh <- interpChar(list(c('Do it', 'with R.')),
                  c(0, .5, .9))
# answer
xCh. <- c('', 'with', 'Do ')
# With only one input, it's assumed to be y.
# It is replicated to length(.proportion),
# With nchar = 5, 7, 5, cum = 5, 12, 17.

all.equal(xCh, xCh.)

##
## 5. Still more complicated
##
xC2 <- interpChar(c('a', 'fabulous', 'bug'),

```

```

      c('bigger or', 'just', 'big'),
      c(.3, .3, 1) )
# answer
x.y.longer <- c('bigger or', 'fabulous', 'big')
# use y with ties
# nch smaller      1      4      3
# nch larger       9      8      3
# d.char           8,     4,     0
# cum characters   8,    12,    12
# prop            .3,    .7,     1
# prop*12         3.6,   8.4,    12
# cum.sm          1,     5,     8
# cum.sm+prop*12  5,    13,    20
# -cum(larger[-1]) 5,     4,     3
xC2. <- c('bigge', 'fabu', 'big')

all.equal(xC2, xC2.)

##
## 6. with one NULL
##
null1 <- interpChar(NULL, 1, 1)

all.equal(null1, 1)

null2 <- interpChar('abc', NULL, .3)

all.equal(null2, 'ab')

##
## 7. length=0
##
log0 <- interpChar(logical(0), 2, .6)

all.equal(log0, 1.2)

##
## 8. Date
##

##
## 9. POSIXct
##

```

## Description

This does two things:

1. Computes a `.proportion` interpolation between pairs by passing each pair with `.proportion` to `interpChar`. `interpChar` does standard linear interpolation with numerics and interpolates based on the number of characters with non-numerics.
2. Discards rows of interpolants for which `.proportion` is outside `validProportion`. If object is a list, corresponding rows of other vectors of the same length are also discarded.

NOTE: There are currently discrepancies between the documentation and the code over defaults when one but not both elements of a pair are provided. The code returns an answer. If that's not acceptable, provide the other half of the pair. After some experience is gathered, the question of defaults will be revisited and the code or the documentation will change.

## Usage

```
interpPairs(object, ...)
## S3 method for class 'call'
interpPairs(object,
  nFrames=1, iFrame=nFrames,
  endFrames=round(0.2*nFrames),
  envir = parent.frame(),
  pairs=c('1'='\\0$', '2'='\\1$',
    replace0='', replace1='.2',
    replace2='.3'),
  validProportion=0:1, message0=character(0), ...)
## S3 method for class 'function'
interpPairs(object,
  nFrames=1, iFrame=nFrames,
  endFrames=round(0.2*nFrames),
  envir = parent.frame(),
  pairs=c('1'='\\0$', '2'='\\1$',
    replace0='', replace1='.2', replace2='.3'),
  validProportion=0:1, message0=character(0), ...)
## S3 method for class 'list'
interpPairs(object,
  .proportion, envir=list(),
  pairs=c('1'='\\0$', '2'='\\1$',
    replace0='', replace1='.2',
    replace2='.3'), validProportion=0:1,
  message0=character(0), ...)
```

## Arguments

object	A <code>call</code> , <code>function</code> , list or <code>data.frame</code> with names possibly matching <code>pairs[1:2]</code> . When names matching both of <code>pairs[1:2]</code> , they are converted to potentially common names using <code>sub(pairs[i], pairs[3], ...)</code> . When matches are found among the potentially common names, they are passed with <code>.proportion</code>
--------	--

to [interpChar](#) to compute an interpolation. The matches are removed and replaced with the interpolant, shortened by excluding any rows for which `.proportion` is outside `validProportion`.

Elements with "common names" that do not have a match are replaced by elements with the common names that have been shortened by omitting rows with `.proportion` outside `validProportion`. Thus, if `x.0` is found without `x.1`, `x.0` is removed and replaced by `x`.

<code>nFrames</code>	number of distinct plots to create.
<code>iFrame</code>	integer giving the index of the single frame to create. Default = <code>nFrames</code> . An error is thrown if both <code>iFrame</code> and <code>.proportion</code> are not NULL.
<code>endFrames</code>	Number of frames to hold constant at the end.
<code>.proportion</code>	a numeric vector assumed to lie between 0 and 1 specifying how far to go from <code>suffixes[1]</code> to <code>suffixes[2]</code> . For example, if <code>x.0</code> and <code>x.1</code> are found and are numeric, $x = x.0 + .proportion * (x.1 - x.0)$ . Rows of <code>x</code> and any other element of object of the same length are dropped for any <code>.proportion</code> outside <code>validProportion</code> . An error is thrown if both <code>iFrame</code> and <code>.proportion</code> are not NULL.
<code>envir</code>	environment / list to use with <code>codeobject</code> , which can optionally provide other variables to compute what gets plotted; see the example below using this argument.
<code>pairs</code>	a character vector of two regular expressions to identify elements of object between which to interpolate and three replacements. (1) The first of the three replacements is used in <a href="#">sub</a> to convert each <code>pairs[1:2]</code> name found to the desired name of the interpolate. Common names found are then passed with <code>.proportion</code> to <a href="#">interpChar</a> , which does the actual interpolation. (2, 3) <code>interpPairs</code> also calls <code>checkNames(object, avoid = pairs[c(1, 3, 2, 5)])</code> . This confirms that object has <code>names</code> , and all such names are unique. If object does not have names or has some duplicate names, the <code>make.names</code> is called to fix that problem, and any new names that match <code>pairs[1:2]</code> are modified using <a href="#">sub</a> to avoid creating a new match. If the modification still matches <code>pairs[1:2]</code> , it generates an error.
<code>validProportion</code>	Range of values of <code>.proportion</code> to retain, as noted with the discussion of the object argument.
<code>message0</code>	a character string passed to <a href="#">interpChar</a> to improve the value of diagnostic messages
<code>...</code>	optional arguments for <a href="#">sub</a>

## Details

\*\*\* FUNCTION \*\*\*

First `interpPairs`.function looks for arguments `firstFrame`, `lastFrame`, and `Keep`. If any of these are found, they are stored locally and removed from the function. If `iFrame` is provided, it is used with with these arguments plus `nFrames` and `endFrames` to compute `.proportion`.

If `.proportion` is outside `validProportion`, `interpPairs` does nothing, returning `enquote(NULL)`.

If `any(.proportion)` is inside `validProportion`, `interpPairs` function next uses `grep` to look for arguments with names matching `pairs[1:2]`. If any are found, they are passed with `.proportion` to `interpChar`. The result is stored in the modified object with the common name obtained from `sub(pairs[i], pairs[3], ...)`, `i = 1, 2`.

The result is then evaluated and then returned.

\*\*\* LIST \*\*\*

1. ALL.OUT: `if(none(0<=.proportion<=1))return 'no.op' = list(fun='return', value=NULL)`
2. FIND PAIRS: Find names matching `pairs[1:2]` using `grep`. For example, names like `x.0` match the default `pairs[1]`, and names like `x.1` match the default `pairs[1]`.
3. MATCH PAIRS: Use `sub(pairs[i], pairs[3], ...)` for `i = 1:2`, to translate each name matching `pairs[1:2]` into something else for matching. For example, the default `pairs` thus translates, e.g., `x.0` and `x.1` both into `x`. In the output, `x.0` and `x.1` are dropped, replaced by `x = interpChar(x.0, x.1, .proportion, ...)`. Rows with `.proportion` outside `validProportion` are dropped in `x`. Drop similar rows of any numeric or character vector or `data.frame` with the same number of rows as `x` or `.proportion`.
4. Add component `.proportion` to `envir` to make it available to `eval` any language component of object in the next step.
5. Loop over all elements of object to create `outList`, evaluating any expressions and computing the desired interpolation using `interpChar`. Computing `xleft` in this way allows `xright` to be specified later as `quote(xleft + xinch(0.6))`, for example. This can be used with a call to `rasterImageAdj`.
6. Let `N =` the maximum number of rows of elements of `outList` created by interpolation in the previous step. If `.proportion` is longer, set `N = length(.proportion)`. Find all vectors and `data.frames` in `outList` with `N` rows and delete any rows for which `.proportion` is outside `validProportion`.
7. Delete the raw pairs found in steps 1-3, retaining the element with the target name computed in steps 4 and 5 above. For other elements of object modified in the previous step, retain the shortened form. Otherwise, retain the original, unevaluated element.

## Value

a list with elements containing the interpolation results.

## Author(s)

Spencer Graves

---

logVarCor	<i>Log-diagonal representation of a variance matrix</i>
-----------	---

---

### Description

Translate a square symmetric matrix with positive diagonal elements into a vector of the logarithms of the diagonal elements with the correlations as an attribute, and vice versa.

### Usage

```
logVarCor(x, corr, ...)
```

### Arguments

x	If a matrix, translate into a vector with a "corr" attribute. If a vector, translate into a matrix.
corr	optional vector of correlations for the <code>lower.tri</code> portion of a covariance matrix whose diagonal is <code>exp(x)</code> . Use a "corr" attribute of x only if this argument is <code>missing</code> .
...	(not currently used)

### Value

`if(length(dim(x))==2)` return `log(diag(x))` with an attribute "corr" equal to the `lower.tri` of `cov2cor(x)`.

Otherwise, return a covariance matrix from x as described above.

### Author(s)

Spencer Graves

### See Also

`log diag cov2cor lower.tri pdLogChol` converts a k-dimensional covariance matrix into a vector of length `choose(k+1, 2)`. By contrast, `logVarCor` returns a vector of length k with a "corr" attribute of length `choose(k, 2)`.

### Examples

```
##
## 1. Trivial 1 x 1 matrix
##
# 1.1. convert vector to "matrix"
mat1 <- logVarCor(1)
# check

all.equal(mat1, matrix(exp(1), 1))
```

```
# 1.2. Convert 1 x 1 matrix to vector
lVCd1 <- logVarCor(diag(1))
# check
lVCd1. <- 0
attr(lVCd1., 'corr') <- numeric(0)

all.equal(lVCd1, lVCd1.)

##
## 2. simple 2 x 2 matrix
##
# 2.1. convert 1:2 into a matrix
lVC2 <- logVarCor(1:2)
# check
lVC2. <- diag(exp(1:2))

all.equal(lVC2, lVC2.)

# 2.2. Convert a matrix into a vector
lVC2d <- logVarCor(diag(1:2))
# check
lVC2d. <- log(1:2)
attr(lVC2d., 'corr') <- 0

all.equal(lVC2d, lVC2d.)

##
## 3. 3-d covariance matrix with nonzero correlations
##
# 3.1. Create matrix
(ex3 <- tcrossprod(matrix(c(rep(1,3), 0:2), 3)))
dimnames(ex3) <- list(letters[1:3], letters[1:3])

# 3.2. Convert to vector
(Ex3 <- logVarCor(ex3))

# check
Ex3. <- log(c(1, 2, 5))
names(Ex3.) <- letters[1:3]
attr(Ex3., 'corr') <- c(1/sqrt(2), 1/sqrt(5), 3/sqrt(10))

all.equal(Ex3, Ex3.)

# 3.3. Convert back to a matrix
Ex3.2 <- logVarCor(Ex3)
# check
```

```
all.equal(ex3, Ex3.2)
```

---

match.data.frame	<i>Identify the row of y best matching each row of x</i>
------------------	--

---

### Description

For each row of `x[, by.x]`, find the best matching row of `y[, by.y]`, with the best match defined by `grep.` and `split.`

`grep.` and `split.` must either be `missing` or have the same length as `by.x` and `by.y`. If `grep.[i]` and `split[i]` are `NA`, do a complete match of `x[, by.x[i]]` and `y[, by.y[i]]`. Otherwise, for each row `j`, look for a match for `strsplit(x[j, by.x[i]], split[i])[[1]][1]` among `strsplit(y[, by.y[i]], split[i])`. See details.

### Usage

```
match.data.frame(x, y, by, by.x=by, by.y=by,
                grep., split, sep='')
```

### Arguments

<code>x, y</code>	<code>data.frames</code>
<code>by, by.x, by.y</code>	names of columns of <code>x</code> and <code>y</code> to match.
<code>grep.</code>	a character vector of the type of match for each element of <code>by.x</code> and <code>by.y</code> . If <code>NA</code> , require a perfect match. Alternatives are <code>grep</code> and <code>agrep</code> to find a match for the first segment in <code>strsplit(x, split=split[i])</code> among any of the segments of <code>strsplit(y, split=split[i])</code> . Use <code>fixed=TRUE</code> with the calls to these functions. NOTE: These alternatives are not examined if a unique match is found between <code>x[, by.x[is.na(grep.) &amp; is.na(split)]]</code> and the corresponding columns of <code>y</code> .
<code>split</code>	A character vector of split characters to pass to <code>strsplit</code> ; <code>strsplit</code> is not called if <code>is.na(split)</code> .
<code>sep</code>	a <code>sep</code> argument to use with <code>paste</code> to produce a matching key for the columns of <code>x</code> and <code>y</code> for which perfect matches are required. If <code>(missing(sep) &amp;&amp; not(missing(grep.)))</code> <code>sep &lt;- ' '</code> except where <code>grep. = NAs</code> .

### Details

1. Check `by.x, by.y, grep.` and `split`. If `((missing(by.x) | missing(by.y)) && missing(by))` `by <- names(x)`
2. `fullMatch <- (is.na(grep.) & is.na(split))`. Create `keyfx` and `keyfy` by pasting columns of `x[, by.x[fullMatch]]` and `y[, by.y[fullMatch]]`. Also create `x.` and `y.` = `strsplit` of `x[, by.x[!fullMatch]]`.

3. Iterate over rows of `x` looking for the best match. This includes an inner loop over columns of `x[, by.x[!fullMatch]]`, stopping on the first unique match. Return `(-1)` if no unique match is found.

### Value

an integer vector of length `nrow(x)` containing the index of the best matching row of `y` or `NA` if no adequate match was found.

### Author(s)

Spencer Graves

### Examples

```
newdata <- data.frame(state=c("AL", "MI", "NY"),
                     surname=c("Rogers", "Rogers", "Smith"),
                     givenName=c("Mike R.", "Mike K.", "Al"),
                     stringsAsFactors=FALSE)
reference <- data.frame(state=c("NY", "NY", "MI", "AL", "NY", "MI"),
                      surname=c("Smith", "Rogers", "Rogers (MI)",
                                "Rogers (AL)", "Smith", 'Jones'),
                      givenName=c("John", "Mike", "Mike", "Mike",
                                   "T. Albert", 'Al Thomas'),
                      stringsAsFactors=FALSE)
newInRef <- match.data.frame(newdata, reference,
                             grep.=c(NA, 'agrep', 'agrep'))

all.equal(newInRef, c(4, 3, 5))
```

---

matchName

*Match surname and givenName in a table*

---

### Description

Use [parseName](#) to split a name into surname and givenName, the look for matches in table.

### Usage

```
matchName(x, data, Names=1:2,
          nicknames=matrix(character(0), 0, 2),
          namesNotFound="attr.replacement", ...)
matchName1(x1, data, name=data[, 1],
           nicknames=matrix(character(0), 0, 2), ...)
```

**Arguments**

x	One of the following: <ul style="list-style-type: none"> <li>• A character matrix or data.frame with the same number of rows as data. The best partial match is sought in Names. The algorithm stops when a unique match is found; any remaining columns of x are then ignored. Any nicknames are ignored for the first column but not for subsequent columns.</li> <li>• A character vector whose length matches the number of rows of data. This will be replaced by parseName(x).</li> </ul>
data	a character matrix or a <a href="#">data.frame</a> . If surname and givenName are character vectors of names, their length must match the number of rows of data.
Names	One of the following in which matches for x will be sought: <ul style="list-style-type: none"> <li>• A character vector or matrix or a data.frame for which <code>NROW(Names) == nrow(data)</code>.</li> <li>• Something to select columns of data to produce a character vector or matrix or data.frame via <code>data[, Names]</code>. In this case, accents will be stripped using <a href="#">subNonStandardNames</a>.</li> </ul>
nicknames	a character matrix with two columns, each row giving a pair of names like "Pete" and "Peter" that should be regarded as equivalent if no exact match(es) is(are) found.
...	optional arguments passed to <a href="#">subNonStandardNames</a>
x1	a character vector of names to match name. NOTE: matchName calls <a href="#">subNonStandardNames</a> , but matchName1 does not. Thus, x1 is assumed to NOT contain characters not in standard English.
name	A character vector or matrix for which <code>NROW(name) == nrow(data)</code> . NOTE: matchName calls <a href="#">subNonStandardNames</a> , but matchName1 does not. Thus, name is assumed to NOT contain characters not in standard English.
namesNotFound	character vector passed to <a href="#">subNonStandardNames</a> and used to compute any namesNotFound attribute of the object returned by <a href="#">parseName</a> .

**Details**

```

*** 1. matchName(x, data, Names, nicknames, ...):
1.1. if(length(dim(x)<2))x <- parseName(x, ...)
1.2. x1 <- matchName1(x[, 1], data, Names[1], ...)
1.3. For any component i of x1 with multiple rows, let x1i <- matchName1(x[i, 2], x1[[i]],
Name[-1], nicknames=nicknames, ...). If nrow(x1i)>0, x1[[i]] <- x1i; else leave unchanged.
1.4. return x1.
=====
*** 2. matchName1(x1, data, name, nicknames, ...):
2.1. If name indicates a column of data, replace with data[, name].
2.2. xsplit <- strsplit(x1, ' ').
2.3. nx <- length(x1); xlist <- vector(nx, mode='list')

```

```

2.4. for(j in 1:nx):
2.5. xj <- xplit[[j]]
2.6. let jd = the subset of names that match xj or subNonStandardNames(xj) or nicknames of xj;
xlist[j] <- jd.
2.7. return xlist

```

### Value

matchName returns a list of the same length as x, each of whose components is an object obtained as a subset of rows of data or NULL if no acceptable matches are found. The list may have an attribute namesNotFound as determined per the argument of that name.

matchNames1 returns a list of vectors of integers for subsets of data matching x1.

---

matchQuote

*Match isolated quotes across records*

---

### Description

Look for unmatched quotes in a character vector. If found, look for a matching quote starting the next character string in the vector, possibly after a blank line. If found, merge the two strings and return the resulting shortened character vector.

### Usage

```

matchQuote(x, Quote="'", sep=' ',
           maxChars2append=2, ...)

```

### Arguments

x	a character vector to scan for unmatched Quotes.
Quote	the Quote character that should appear in pairs
sep	sep argument passed to <a href="#">paste</a> to combine pairs of successive lines with unmatched quotes.
maxChars2append	maximum number of characters in the following string to concatenate two adjacent strings (possibly separated by a blank line) with unmatched Quotes.
...	optional arguments for <a href="#">gsub</a>

### Details

This function was written to help parse data from the US Department of Health and Human Services on [cyber-security breaches affecting 500 or more individuals](#). As of 2014-06-03 the csv version of these data included commas in quotes that are not sep characters, quotes that are not matched, lines with zero characters, followed by lines with 3 characters being a quote and a comma. This function was written to drop the blank lines and append the quote-comma line to the preceding line so it contained matching quotes.

**Value**

The input character vector possibly shortened with the following attributes explaining what was found:

indices of the input `x` with an unmatched

- `unmatchedQuotes` Quote.
- `blankLinesDropped` indices of the input `x` that were dropped because they (1) followed an unmatched Quote and (2) contained no non-blank characters.
- `quoteLinesAppended` indices of the input `x` that were concatenated with a preceding line because the two lines contained unmatched Quote characters, and concatenating them produced a line with all Quotes matched.
- `ncharsAppended` an integer vector of the same length as `quoteLinesConcatenated` giving the number of characters in the second line concatenated onto the previous line.

**Examples**

```
chvec <- c('abc', 'de" f', ' ', '"', 'g" h',
          'matched"quotes"', '')
ch. <- matchQuote(chvec)

# check
chv. <- c('abc', 'de" f "', 'g" h',
         'matched"quotes"', '')
attr(chv., 'unmatchedQuotes') <- c(2, 4, 5)
attr(chv., 'blankLinesDropped') <- 3
attr(chv., 'quoteLinesAppended') <- 4
attr(chv., 'ncharsAppended') <- 2

all.equal(ch., chv.)
```

---

mergeVote

*Merge Roll Call Vote*

---

**Description**

Merge roll call vote record with a [data.frame](#) containing other information. The vote records are typically incomplete, so match first on `houseSenate` and `surname`. If this match is incomplete, try using `givenName`. If that fails, try `state` and `district`, which may not always be present in `vote`.

## Usage

```
mergeVote(x, vote, Office="House", vote.x,  
          check.x=TRUE)
```

## Arguments

x	a <a href="#">data.frame</a> whose columns include Office, surname, and givenName.
vote	a <a href="#">data.frame</a> with column names which when forced <a href="#">tolower</a> would match surname, givenname, and vote. However, the givenname may not be complete, so use it only if the surname is not sufficient.
Office	Either "House" or "Senate"; ignored if vote includes a column Office.
vote.x	name of a column of x containing a vote to be updated with the vote column of the vote <a href="#">data.frame</a> . If <a href="#">missing</a> and x has a column with a name matching "vote", then vote.x is that column. If <a href="#">missing</a> but x has no such column, then append a column to x with the name of the vote column of the vote <a href="#">data.frame</a> .
check.x	logical: If TRUE, check for rows of x[, vote.x] that are NOT in vote and throw an error if found.

## Details

1. Parse vote.x to get the name of the column of x into which to write the vote column of the vote [data.frame](#).
2. If the vote [data.frame](#) contains a column Office, ignore the Office argument. Otherwise, add the argument houseSenate as a column of vote.
3. Create keyx <- with(x, paste(Office, surname, sep=":")), keyx2 <- paste(keyx, givenName, sep=":"), keyx. <- paste(houseSenate, state, district, sep=":"), and similarly keyv, leyv2, and keyv. from vote.
4. Look for keyv in keyx. When a unique match is found, transfer the vote the vote column of x. When no match is found, try for keyv2 in keyx2 or keyv. in keyx. If those fail, print an error message with the information from vote on all failures and ask the user to add state and district information.
5. if(check.x), check for rows in x[, vote.x] that are NOT notEligible but are also not in vote: Throw an error if any are found.

## Value

a [data.frame](#) with the same columns as x with its vote column modified per the vote argument.

## Author(s)

Spencer Graves

```

```
all.equal(nchar0(c('a', 'c')), FALSE)
```

Newdata

*Create a new data.frame for predict***Description**

Generate a new `data.frame` or `matrix` from another with column(s) selected by `x` adopting `n` values in `range(data[,x])` and all other columns constant.

If `canbeNumeric(x)` is TRUE, the output has `x` adopting `n` values in the `range(x)` and all other numeric variables at their `median` and other variables at their most common values.

If `canbeNumeric(x)` is FALSE, the output has `x` adopting all possible values of `x` with all other variables at the same constant values as when `canbeNumeric(x)` is TRUE (and `n` is ignored). If `x` has a `levels` attribute, the possible values are defined by that `levels` attribute. Otherwise, it is defined by `unique(x)`.

This is designed to create a new `data.frame` to be used as `newdata` for `predict`.

**Usage**

```
Newdata(data, x, n, na.rm=TRUE)
```

**Arguments**

<code>data</code>	a <code>data.frame</code> or matrix.
<code>x</code>	name of a column of data. If NA or NULL, select all columns of data.
<code>n</code>	an <code>integer</code> vector indicating the number of levels of <code>data[, x]</code> if <code>canbeNumeric(data[, x])</code> is TRUE. If <code>canbeNumeric(data[, x])</code> is FALSE, take at most <code>n</code> of the most popular levels. Default is 2 if <code>length(x) &gt; 1</code> or if <code>x</code> is either NA or NULL. If <code>n = 1</code> , use the median for <code>canbeNumeric</code> and the most popular level otherwise. If <code>n &lt; 1</code> , drop that variable.
<code>na.rm</code>	<code>logical</code> passed to <code>range(x)</code>

**Details**

1. Check `data, x`.
2. If `canbeNumeric(x)` is TRUE, let `xNew` be `n` values spanning `range(x)`. Else, let `xNew <- levels(x)`.
3. If `is.null(xNew)`, set it to `sort(unique(x))`.
4. let `newDat <- data[rep(1, n), ]`, and replace `x` by `xNew`.
5. `otherVars <- colnames(data) != x`
6. for(`x2` in `otherVars`) replace `newDat[, x2]`: If `canbeNumeric(x2)` is TRUE, use `median(x2)`. Otherwise, use its (first) most common value.

**Value**

A `data.frame` with `n` rows and columns matching those of `data`, as described above.

**Author(s)**

Spencer Graves

**See Also**[predict.lm](#)**Examples**

```

---

parseCommas

*Convert character string with Dollar signs and commas to numerics*

---

### Description

as.numeric of character strings after suppressing commas and dollar signs. This is a generalization of [parseDollars](#).

### Usage

```

parseCommas(x, pattern='\\$|,',
  replacement='', acceptableErrorRate=0, ...)
## Default S3 method:
parseCommas(x,
  pattern='\\$|,', replacement='',

```

```

    acceptableErrorRate=0, ...)
## S3 method for class 'data.frame'
parseCommas(x,
  pattern='\\$|,', replacement='',
  acceptableErrorRate=0, ...)

```

### Arguments

**x** vector of character strings to be converted to numerics

**pattern** regular expression to be replaced by replacement

**replacement** Character string to substitute for each occurrence of pattern

**acceptableErrorRate** number indicating the proportion of new NAs to that can be introduced and still assume it's numeric

**...** optional arguments to pass to [gsub](#)

### Details

```
as.numeric(gsub(x, ...))
```

The [data.frame](#) method outputs another [data.frame](#) with character or factor columns converted to numerics using [parseDollars](#) whenever that can be done without creating NAs.

### Value

Numeric vector converted from the character strings in **x** or a [data.frame](#) with columns that are obviously numbers in character format converted to numerics.

### Author(s)

Spencer Graves

### See Also

[gsub](#) [as.numeric](#) [parseDollars](#)

### Examples

```

##
## 1. a character vector
##
X2 <- c('-2,500', '$5,000.50')

all.equal(x2, c(-2500, 5000.5))

##
## A data.frame

```

```
##
chDF <- data.frame(let=letters[1:2], Dol=X2, dol=x2)
numDF <- parseCommas(chDF)

chkDF <- chDF
chkDF$Dol <- x2

all.equal(numDF, chkDF)
```

---

parseDollars

*Convert character string with Dollar signs and commas to numerics*

---

### Description

as.numeric of character strings after suppressing commas and dollar signs. This is a special case of [parseCommas](#).

### Usage

```
parseDollars(x, pattern='\\$|,',
             replacement='', ...)
```

### Arguments

x	vector of character strings to be converted to numerics
pattern	regular expression to be replaced by replacement
replacement	Character string to substitute for each occurrence of pattern
...	optional arguments to pass to <a href="#">gsub</a>

### Details

as.numeric(gsub(x, ...)). See also [parseCommas](#).

### Value

Numeric vector converted from x.

### Author(s)

Spencer Graves

### See Also

chkDF <- chDF
chkDF$Dol <- x2

all.equal(numDF, chkDF)
```

---

parseName	<i>Parse surname and given name</i>
-----------	-------------------------------------

---

**Description**

Identify the presumed surname in a character string assumed to represent a name and return the result in a character matrix with surname followed by givenName. If only one name is provided (without punctuation), it is assumed to be the givenName; see Wikipedia, "[Given name](#)" and "[Surname](#)".

**Usage**

```
parseName(x,
  surnameFirst=(median(regexpr(' ', x))>0),
  suffix=c('Jr.', 'I', 'II', 'III', 'IV',
           'Sr.', 'Dr.', 'Jr', 'Sr'),
  fixNonStandard=subNonStandardNames,
  removeSecondLine=TRUE,
  namesNotFound="attr.replacement", ...)
```

**Arguments**

x                    a character vector

surnameFirst	logical: If TRUE, the surname comes first followed by a comma (","), then the given name. If FALSE, parse the surname from a standard Western "John Smith, Jr." format. If missing(surnameFirst), use TRUE if half of the elements of x contain a comma.
suffix	character vector of strings that are NOT a surname but might appear at the end without a comma that would otherwise identify it as a suffix.
fixNonStandard	function to look for and repair nonstandard names such as names containing characters with accent marks that are sometimes mangled by different software. Use <a href="#">identity</a> if this is not desired.
removeSecondLine	logical: If TRUE, delete anything following "\n" and return it as an attribute secondLine.
namesNotFound	character vector passed to subNonStandardNames and used to compute any namesNotFound attribute of the object returned by parseName.
...	optional arguments passed to fixNonStandard

### Details

If surnameFirst is FALSE:

1. If the last character is ")" and the matching "(" is 3 characters earlier, drop all that stuff. Thus, "John Smith (AL)" becomes "John Smith".
2. Look for commas to identify a suffix like Jr. or III; remove and call the rest x2.
3. `split <- strsplit(x2, " ")`
4. Take the last as the surname.
5. If the "surname" found per 3 is in suffix, save to append it to the givenName and recurse to get the actual surname.

NOTE: This gives the wrong answer with double surnames written without a hyphen in the Spanish tradition, in which, e.g., "Anastasio Somoza Debayle", "Somoza Debayle" give the (first) surnames of Anastasio's father and mother, respectively: The current algorithm would return "Debayle" as the surname, which is incorrect.

6. Recompose the rest with any suffix as the givenName.

### Value

a character matrix with two columns: surname and givenName.

This matrix also has a namesNotFound attribute if one is returned by subNonStandardNames.

all.equal(noSub, noSub.)

```

---

Ping

*ping a Uniform resource locator (URL)*

---

## Description

\*\*\*NOTE: THIS IS A PRELIMINARY VERSION OF THIS FUNCTION; \*\*\*NOTE: IT MAY BE CHANGED OR REMOVED IN A FUTURE RELEASE.

ping a Uniform resource locator (URL) or Internet Protocol (IP) address.

NOTE: Some Internet Service Providers (ISPs) play games with "ping". That makes the results of Ping unreliable.

**Usage**

```
Ping(url, pingArgs='', warn=NA,  
      show.output.on.console=FALSE)
```

**Arguments**

`url` a character string of a URL or IP address to ping. If `url` is a vector of length greater than 1, only the first component is used.

`pingArgs` arguments to pass to the ping command of typical operating systems via `pingResult <- system(paste('ping', pingArgs, url), intern=TRUE, ...)`

`warn` value for `options('warn')` during the call to `system`. NA to not change `options('warn')` during this call.

`show.output.on.console` argument for `system`.

**Details**

```
1. urlSplit0 <- strsplit(url, '://')[[1]]  
2. urlS0 <- urlSplit0[min(2, length(urlSplit0))]  
3. host <- strsplit(urlS0, '/')[[1]][1]  
4. pingCmd <- paste('ping', pingArgs, host)  
5. system(pingCmd, intern=TRUE, ...)
```

**Value**

list with the following components:

`rawResults` character vector of the raw results from the ping command

`rawNumbers` numeric vector of the times measured

`counts` numeric vector of numbers of packets sent, received, and lost

`p.lost` proportion lost = lost / sent

`stats` numeric vector of min, avg (mean), max, and mdev (standard deviation) of the measured round trip times

**Author(s)**

Spencer Graves

**See Also**

[system](#), [options](#)

**Examples**

```
##
## Some ISPs play games with ping.
## Therefore, the results are not reliable.
##
## Not run:
##
## good
##
(google <- Ping('https://google.com/ping works on host not pages'))

\dontshow{stopifnot()}
with(google, (counts[1]>0) && (counts[3]<1))
\dontshow{}}

##
## ping oops <<-- at one time, this failed.
##     However, with some ISPs, it works, so don't test it.
##
##
(couldnotfindhost <- Ping('oops'))

\dontshow{stopifnot()}
with(couldnotfindhost,
     length(grep('could not find host', rawResults))>0)
\dontshow{}}

##
## impossible, but not so obvious
##
(requesttimedout <- Ping('requesttimedout.com'))

\dontshow{stopifnot()}
with(requesttimedout, (counts[1]>0) && (counts[2]<1) &&
                     (counts[3]>0))
\dontshow{}}

## End(Not run)
```

---

pmatch2

*Value matching or partial matching*

---

**Description**

pmatch2 returns a list of the positions of matches or partial matches of x in table.

This does sloppy matching to find "Peter" to match "Pete" only if "Pete" is not in table, and we want "John Peter" if neither "Pete" nor "Peter" are in table.

**Usage**

```
pmatch2(x, table)
```

**Arguments**

x	the values to be matched
table	the values to be matched against

**Details**

1. nx <- length(x); out <- vector(nx, "list"); names(out) <- x
2. for(ix in seq(length=nx)): 3. xi <- which(x[ix] %in% table)
4. if(length(xi)<1) xi <- grep(paste0('^', x[ix]), table).
5. if(length(xi)<1)xi <- grep(x[ix], table).
6. out[[ix]] <- xi

**Value**

A list of integer vectors indicating the positions in table matching each element of x

**Author(s)**

Spencer Graves

**See Also**

[match](#) [pmatch](#) [grep](#) [matchName](#)

**Examples**

```
##
## 1. common examples
##
x2match <- c('Pete', 'Peter', 'Ma', 'Mo', 'Paul',
             'Cardenas')

tbl <- c('Peter', 'Mary', 'Martha', 'John Paul', 'Peter',
        'Cardenas', 'Cardenas')

x2mtchd <- pmatch2(x2match, tbl)

# answer
x2mtchd. <- list(Pete=c(1, 5), Peter=c(1, 5), Ma=2:3,
               Mo=integer(0), Paul=4, Cardenas=6:7)

all.equal(x2mtchd, x2mtchd.)

##
## 2. strange cases that caused errors and are now warnings
```

```
##
huh <- pmatch2("7", tbl)

# answer
huh. <- list("7"=integer(0))

all.equal(huh, huh.)
```

---

pmatchIC

*pmatch ignoring case*

---

### Description

pmatch with an additional ignoreCase argument, returning a name not an index like [pmatch](#) (and returning a name if supplied a number, unlike [pmatch](#), which coerces the input to numeric).

### Usage

```
pmatchIC(x, table, nomatch = NA_integer_,
         duplicates.ok = FALSE,
         ignoreCase=TRUE)
```

### Arguments

x	the values to be matched. If <code>is.numeric(x)</code> , <code>pmatch2</code> returns <code>table[x]</code> . This is different from <a href="#">pmatch</a> , which matches as <code>as.character(x)</code> . Otherwise, if <code>ignoreCase</code> is <code>TRUE</code> , <code>pmatchIC</code> returns <code>pmatch(tolower(x), tolower(table))</code> .
table	the values to be matched against: converted to a character vector, per <a href="#">pmatch</a> .
nomatch	the value to be returned at non-matching or multiply partially matching positions.
duplicates.ok	should elements be in table be used more than once? (See <a href="#">pmatch</a> for an example.)
ignoreCase	logical: if <code>TRUE</code> and <code>x</code> is character, <code>pmatchIC</code> returns <code>pmatch(tolower(x), tolower(table))</code> .

### Value

A character vector of matches.

### Author(s)

Spencer Graves

### See Also

[pmatch](#)

**Examples**

```

yr <- pmatchIC('Yr', c('y1', 'yr', 'y2'))

all.equal('yr', yr)

# integer
m2 <- pmatchIC(2, table=letters)

all.equal(m2, 'b')

```

---

qqnorm2

*Normal Probability Plot with Multiple Symbols*

---

**Description**

Create a normal probability plot with one line and different symbols for the values of another variable, *z*.

qqnorm2 produces an object of class qqnorm2, whose plot method produces the plot.

To create a normal normal probability plots with multiple lines, see [qqnorm2t](#) or [qqnorm2s](#): *x*.

- [qqnorm2s](#) produces a plot with multiple lines specified either by different names in a character vector *y* or by different [data.frames](#) in a list *data.*, with different points labeled according to the different levels of *z*.
- [qqnorm2t](#) produces a plot with multiple lines with *y* split on different levels of *x*, optionally with different points labeled according to different levels of *z*.

**Usage**

```

qqnorm2(y, z, plot.it=TRUE, datax=TRUE, pch=NULL,
        ...)
## S3 method for class 'qqnorm2'
plot(x, y, ...)
## S3 method for class 'qqnorm2'
lines(x, ...)
## S3 method for class 'qqnorm2'
points(x, ...)

```

**Arguments**

*y* For qqnorm2, *y* is a numeric vector for which a normal probability plot is desired. For plot.qqnorm2, *y* is ignored; it is included, because the generic [plot](#) function requires it.

z	A variable to indicate different plotting symbols. NOTE: <code>is.logical(z)</code> is replaced by <code>z &lt;- as.character(z)</code> . Otherwise, <code>pch[z]</code> would delete symbols in <code>pch</code> for which <code>z</code> is <code>FALSE</code> and would recycle the remaining symbols. That would rarely be what we want.
plot.it	logical: Should the result be plotted?
datax	The <code>datax</code> argument of <code>qqnorm</code> : If <code>TRUE</code> , the data are displayed on the horizontal rather than the vertical axis. (The default value for <code>datax</code> is the opposite of that for <code>qqnorm</code> .)
x	an object of class <code>qqnorm2</code> .
pch	a named vector of the plotting symbols to be used with names corresponding to the levels of <code>z</code> . If <code>pch</code> is provided, it must either have names corresponding to levels of <code>z</code> , or <code>z</code> must be integers between 1 and <code>length(pch)</code> . Otherwise, if <code>z</code> takes levels <code>FALSE</code> and <code>TRUE</code> (or 0 and 1), <code>pch=c(4, 1)</code> to plot an "x" for <code>FALSE</code> and "o" for <code>TRUE</code> . Or if <code>z</code> assumes integer values between 0 and 255, by default, the symbols are chosen as described with <code>points</code> . NOTE: <code>*** points.qqnorm2</code> may not work properly for <code>z</code> being integer between 0 and 255. <code>lines.qqnorm2</code> is more likely to work in such cases. <code>***</code> No time to fix this as of 2018-01-20. Otherwise, by default, <code>z</code> is coerced to <code>character</code> , and the result is plotted.
...	Optional arguments. For <code>plot.qqnorm2</code> , they are passed to <code>plot</code> . For <code>qqnorm2</code> , they are passed to <code>qqnorm</code> and to <code>plot.qqnorm2</code> .

## Details

For `qqnorm2`:

```
qq1. q2 <- qqnorm(y, datax=datax, ...)
```

```
qq2. q2[["z"]] <- z
```

```
qq3. q2[["pch"]] gets whatever pch decodes to.
```

```
qq4. Silently return(list(x, y, z, pch, ...)), where x and y are as returned by qqnorm in step 1 above. If pch is not provided and z is not logical or positive integers, then z itself will be plotted and pch will not be in the returned list.
```

For `plot.qqnorm2`:

```
plot1. plot(x$x, x$y, type="n", ...) with ... taking precedence over x, where the same plot argument appears in both.
```

```
plot2. if(type %in% c('l', 'b', 'c', 'o')) lines(x$x, x$y, ...)
```

```
plot3. if(type %in% c('p', 'b', 'o')): if(is.null(x$z))points(x$x, x$y, ...) else
if(is.logical(x$z)) points(x$x, x$y, pch=x$pch[x$z], ...) else if(is.numeric(x$z)
&& (min(z0 <- round(x$z))>0) && (max(abs(x$z-z0))<10*.Machine$double.eps)) points(x$x,
x$y, pch=x$pch[x$z], ...) else text(x$x, x$y, x$z, ...)
```

```
For lines.qqnorm2 lines1. if(type != 'p')lines(x$x, x$y, ...);
```

```
lines2. if(type %in% c('p', 'b', 'o')) if(is.null(pch))text(x$x, x$y, x$z, ...) else
if(is.character(pch)) text(x$x, x$y, x$pch[x$z], ...) else points(x$x, x$y, pch=x$pch[x$z],
...)
```

```
For points.qqnorm2 points1. if(type %in% c('p', 'b', 'o')) if(is.null(pch))text(x$x,
x$y, x$z, ...) else if(is.character(pch)) text(x$x, x$y, x$pch[x$z], ...) else
points(x$x, x$y, pch=x$pch[x$z], ...)
```

```
points2. if(!(type %in% c('p', 'n')) lines(x$x, x$y, ...)
```

### Value

qqnorm2 returns a list with components, x, y, z, and pch.

---

qqnorm2s

*Normal Probability Plot with Multiple Lines and Multiple Symbols*

---

## Description

Create a normal probability plot with one line for each y variable or each [data.frame](#) in a list data. with different plotting symbols for the values of z.

To create a normal probability plot with one y variable split on a [link{factor}](#) or [character](#) variable x, see [qqnorm2t](#).

qqnorm2s produces an object of class qqnorm2s, whose plot method produces the plot.

## Usage

```

qqnorm2s(y, z=NULL, data., plot.it=TRUE,
         datax=TRUE, outnames=NULL, pch=NULL,
         col=c(1:4, 6), legend.=NULL, ...)
## S3 method for class 'qqnorm2s'
plot(x, y, ...)

```

## Arguments

y a [character](#) vector of names of columns of data. for which normal probability plots are desired. data. is either a [data.frame](#) or a list of [data.frames](#) of the same length as y, with y[i] being the name of a column of the [data.frame](#) data.[[i]]. z is a similar character vector of names of columns of data., which identify symbols for plotting different points in a normal probability plot.

	The lengths of <code>y</code> , and <code>z</code> must match the number of <code>data.frames</code> in <code>data.</code> ; if not, the lengths of the shorter are replicated to the length of the longest before computations begin.
	For <code>plot.qqnorm2s</code> , <code>y</code> is ignored; it is included, because the generic <code>plot</code> function requires it.
<code>z</code>	A character vector giving the names of columns of <code>data.</code> to indicate different plotting symbols. <code>z</code> should be the same length as <code>y</code> and must equal the number of <code>data.frames</code> in the list <code>data.</code> of <code>data.frames</code> . If not, the shorter are replicated to the length of the longer.
<code>data.</code>	a <code>data.frame</code> or a list of <code>data.frames</code> with columns named in <code>y</code> and <code>z</code> .
<code>plot.it</code>	logical: Should the result be plotted?
<code>datax</code>	The <code>datax</code> argument of <code>qqnorm</code> : If TRUE, the data are displayed on the horizontal rather than the vertical axis. (The default value for <code>datax</code> is the opposite of that for <code>qqnorm</code> .)
<code>outnames</code>	Names for the components of the <code>qqnorm2s</code> object returned by the <code>qqnorm2s</code> function.
<code>pch</code>	a named vector of the plotting symbols to be used with names corresponding to the levels of <code>z</code> . By default, if <code>z</code> takes levels FALSE and TRUE (or 0 and 1), <code>pch=c(4, 1)</code> to plot a "x" for FALSE and "o" for TRUE. If <code>z</code> assumes integer values between 0 and 255, by default, the symbols are chosen as described with <code>points</code> . Otherwise, by default, <code>z</code> is coerced to <code>character</code> , and the result is plotted. If <code>pch</code> is provided, it must either have names corresponding to levels of <code>z</code> , or <code>z</code> must be integers between 1 and <code>length(pch)</code> .
<code>col</code>	A vector indicating the colors corresponding to each element of <code>y</code> . Defaults to <code>rep(c(1:4, 6), length=length(y))</code> , with 1:4 and 6 being black, red, green, blue, and pink.
<code>x</code>	an object of class <code>qqnorm2</code> .
<code>legend.</code>	A list with components <code>pch</code> and <code>col</code> providing information for <code>legend</code> to identify the plotting symbols ( <code>pch</code> ) and colors ( <code>col</code> ). By default, <code>pch = list(x='right', legend=names(qq2s[[1]][['pch']]), pch=qq2s[[1]][['pch']])</code> , where <code>qq2s</code> is described below in details. Similarly, by default, <code>lines = list(x='bottomright', legend=y, lty=1, pch=NA, col=qq2s[[1]][['col']])</code> .
<code>...</code>	Optional arguments. For <code>plot.qqnorm2s</code> , they are passed to <code>plot</code> . For <code>qqnorm2s</code> , they are passed to <code>qqnorm2</code> and to <code>plot.qqnorm2s</code> .

## Details

For `qqnorm2s`:

1. Create `qq2s = a list of objects of class qqnorm2`
2. Add `legend.` to `qq2s`.

3. `class(qq2s) <- 'qqnorm2s'`
4. `if(plot.it)plot(qq2s, ...)`
5. Silently return(`qq2s`).

For `plot.qqnorm2s`, create a plot with one line for each variable named in `y`.

### Value

`qqnorm2s` returns a named list with components of class `qqnorm2` with names = `y` with each component having an additional component `col` plus one called "legend."

### Author(s)

Spencer Graves

---

qqnorm2t

*Normal Probability Plot with Multiple Lines and Multiple Symbols*

---

## Description

Create a normal probability plot of  $y$  with one line for each level of a [factor](#) or [character](#) variable  $x$  and (optionally) different symbols for the different levels of a variable  $z$ .

To create a normal probability plot with one line for each of multiple  $y$  variables, see [qqnorm2s](#).

To create a normal probability plot with one line and different symbols for each level of a variable  $z$ , see [qqnorm2](#).

## Usage

```
qqnorm2t(y, x, z=NULL, data., plot.it=TRUE,
  datax=TRUE, outnames=NULL, pch=NULL,
  col=c(1:4, 6), legend.=NULL, ...)
```

## Arguments

$y$	a <a href="#">character</a> vector of length 1 with the name of a column of data. for which normal probability plots are desired, with one line for each level of $x$ .
$x$	a <a href="#">factor</a> or <a href="#">character</a> vector indicating how to split $y$ for plotting.
$z$	A character vector giving the name of a column of data. to indicate different plotting symbols.
$data.$	a <a href="#">data.frame</a> with columns named in $y$ , $x$ , and $z$ .
$plot.it$	logical: Should the result be plotted?

datax	The datax argument of <a href="#">qqnorm</a> : If TRUE, the data are displayed on the horizontal rather than the vertical axis. (The default value for datax is the opposite of that for <a href="#">qqnorm</a> .)
outnames	Names for the components of the qqnorm2s object returned by the qqnorm2s function. Equal to the levels of x by default.
pch	a named vector of the plotting symbols to be used with names corresponding to the levels of z.  By default, if z takes levels FALSE and TRUE (or 0 and 1), pch=c(4, 1) to plot a "x" for FALSE and "o" for TRUE.  If z assumes integer values between 0 and 255, by default, the symbols are chosen as described with <a href="#">points</a> .  Otherwise, by default, z is coerced to <a href="#">character</a> , and the result is plotted.  If pch is provided, it must either have names corresponding to levels of z, or z must be integers between 1 and length(pch).
col	A vector indicating the colors corresponding to each element of x. Defaults to rep(c(1:4, 6), length=length(x)), with 1:4 and 6 being black, red, green, blue, and pink.
legend.	A list with components pch and col providing information for <a href="#">legend</a> to identify the plotting symbols (pch) and colors (col).  By default, pch = list(x='right', legend=names(qq2s[[1]][['pch']])), pch=qq2s[[1]][['pch']], where qq2s is described below in details.  Similarly, by default, lines = list(x='bottomright', legend=y, lty=1, pch=NA, col=qq2s[[1]][['col']]).
...	Optional arguments.  For plot.qqnorm2s, they are passed to plot.  For qqnorm2s, they are passed to <a href="#">qqnorm2</a> and to plot.qqnorm2s.

**Details**

data. is split by x and the result is passed to qqnorm2s

**Value**

Returns an object of class [qqnorm2s](#).

**Author(s)**

Spencer Graves

## Examples

```
##
## One data.frame
##
tstDF2 <- data.frame(y=1:6, x=c('a','b'),
  z2=c(TRUE, TRUE, FALSE),
  z3=c('tell', 'me', 'why') )
# produce the object and plot it
Qnt <- qqnorm2t('y', 'x', 'z2', tstDF2)

# plot the object previously created
plot(Qnt)

Qnt0 <- qqnorm2t('y', 'x', data.=tstDF2)
# without z
qqnorm2t('y', 'x', data.=tstDF2)
```

---

rasterImageAdj

*rasterImage adjusting to zero distortion*

---

## Description

Call `rasterImage` to plot image from  $(x_{\text{left}}, y_{\text{bottom}})$  to either  $x_{\text{right}}$  or  $y_{\text{top}}$ , shrinking one toward the center to avoid distortion.

`angle` specifies a rotation around the midpoint  $((x_{\text{left}}+x_{\text{right}})/2, (y_{\text{bottom}}+y_{\text{top}})/2)$ . This is different from `rasterImage`, which rotates around  $(x_{\text{left}}, y_{\text{bottom}})$ .

NOTE: The code may change in the future. The visual image with rotation looks a little off in the examples below, but the code seems correct. If you find an example where this is obviously off, please report to the maintainer – especially if you find a fix for this.

## Usage

```
rasterImageAdj(image, xleft=par('usr')[1],
  ybottom=par('usr')[3], xright=par('usr')[2],
  ytop=par('usr')[4], angle = 0, interpolate = TRUE,
  xsub=NULL, ysub=NULL, ...)
```

## Arguments

<code>image</code>	a raster object, or an object that can be coerced to one by <code>as.raster</code> .
<code>xleft</code>	a vector (or scalar) of left x positions.
<code>ybottom</code>	a vector (or scalar) of bottom y positions.
<code>xright</code>	a vector (or scalar) of right x positions.
<code>ytop</code>	a vector (or scalar) of top y positions.

angle	angle of rotation in degrees, anti-clockwise about the centroid of image. NOTE: <code>rasterImage</code> rotates around (xleft, ybottom). <code>rasterImage</code> rotates around the center $((xleft+xright)/2, (ybottom+ytotop)/2)$ . See the examples.
interpolate	a logical vector (or scalar) indicating whether to apply linear interpolation to the image when drawing.
xsub, ysub	subscripts to subset image
...	graphical parameters (see <code>par</code> ).

### Details

1. `imagePixels` = number of (x, y) pixels in image. Do this using `dim(as.raster(image))[2:1]`, because the first dimension of `image` can be either x or y depending on `class(image)`. For example `link[EBImage]{Image}` returns `dim` with x first then y and an optional third dimension for color. A simple 3-dimensional array is assumed by `rasterImage` to have the y dimension first. `as.raster` puts all these in a standard format with y first, then x.
2. `imageUnits` <- c(x=xright-xleft, y=top-ybottom)
3. `xyinches` = (x, y) units per inch in the current plot, obtained from `xyinch`.
4. Compute pixel density (pixels per inch) in both x and y dimension: `pixelsPerInch` <- `imagePixels` \* `xyinches` / `imageUnits`.
5. Compute `imageUnitsAdj` solving 4 for `imageUnits` and replacing `pixelsPerInch` by the max pixel density: `imageUnitsAdj` <- `imagePixels` \* `xyinches` / `max(pixelsPerInch)`.
6. (dX, dY) = `imageUnitsAdj`/2 = half of the (width, height) in plotting units.
7. `cntr` = (xleft, ybottom) + (dX, dY).  
`xleft0` = `cntr`[1]+`sin`((`angle`-90)\*`pi`/180)\*`dX`\*`sqrt`(2);  
`ybottom0` = `cntr`[2]-`cos`((`angle`-90)\*`pi`/180)\*`dY`\*`sqrt`(2);  
(`xright0`, `ytotop0`) = (upper right without rotation about lower left)  
`xright0` = `xleft0`+`imageUnitsAdj`[2]  
`ytotop0` = `ybottom0`+`imageUnitsAdj`[2]
8. `rasterImage(image, xleft0, ybottom0, xright0, ytotop0, angle, interpolate, ...)`

### Value

a named vector giving the values of `xleft`, `ybottom`, `xright`, and `ytotop` passed to `rasterImage`. (`rasterImage` returns NULL, at least for some inputs.) This shows the adjustment, shrinking toward the center and rotating as desired.

  }
}

```

---

read.transpose	<i>Read a data table in transpose form</i>
----------------	--

---

### Description

Read a text (e.g., csv) file, find rows with more than 3 sep characters. Parse the initial contiguous block of those into a matrix. Add attributes headers, footers, and a summary.

The initial application for this function is to read Table 6.16. Income and employment by industry in the National Income and Product Account tables published by the Bureau of Economic Analysis of the United States Department of Commerce.

### Usage

```
read.transpose(file, header=TRUE, sep=',',
              na.strings='---', ...)
```

### Arguments

file	the name of a file from which the data are to be read.
header	Logical: Is the second column of the identified data matrix to be interpreted as variable names?
sep	The field space separator character.
na.strings	character string(s) that translate into NA
...	optional arguments for <a href="#">strsplit</a>

### Details

1. txt <- readLines(file)
2. Split into fields.
3. Identify headers, Data, footers.
4. Recombine the second component of each Data row if necessary so all have the same number of fields.
5. Extract variable names
6. Numbers?
7. return the transpose

### Value

A matrix of the transpose of the rows with the max number of fields with attributes headers, footers, other, and summary. If this matrix can be coerced to numeric with no NAs, it will be. Otherwise, it will be left as character.

# to ensure the code will handle commas in a name
# and NAs
nipa6.16D <- read.transpose(demoCsv[4])
str(nipa6.16D)
```

---

readDates3to1

*read.csv with Dates in 3 columns*

---

**Description**

[read.csv](#), converting 3-column dates into vectors of class Date.

**Usage**

```
readDates3to1(file, YMD=c('Year', 'Month', 'Day'),
              ...)
```

**Arguments**

file	the name of a file from which the data are to be read.
YMD	Character vector of length 3 passed to <a href="#">dateCols</a>
...	optional arguments for <a href="#">read.csv</a>

**Details**

Some files (e.g., from the [Correlates of War](#) project) have dates specified in three separate columns with names like `startMonth1`, `startDay1`, `startYear1`, `endMonth1`, ..., `endYear2`. This function looks for such triples and replaces each found with a single column with a name like, `start1`, `end1`, ..., `end2`.

**ALGORITHM**

1. `dat <- read.csv(file, ...)`
2. `Dates3to1(dat, YMD)`

**Value**

a `data.frame` with 3-column dates replace by single-column vectors of class `Date`.

**Author(s)**

Spencer Graves

[read.csv](#) [Dates3to1](#) [dateCols](#)

**Examples**

```
##
## 1. Write a file to be read
##
cow0 <- data.frame(rec=1:3, startMonth=4:6,
  startDay=7:9, startYear=1971:1973,
  endMonth1=10:12, endDay1=13:15,
  endYear1=1974:1976, txt=letters[1:3])

cowFile <- tempfile('cow0')
write.csv(cow0, cowFile, row.names=FALSE)
##
## 2. Read it
##
cow0. <- readDates3to1(cowFile)

# check
cow0x <- data.frame(rec=1:3, txt=letters[1:3],
  start=as.Date(c('1971-04-07', '1972-05-08', '1973-06-09')),
  end1=as.Date(c('1974-10-13', '1975-11-14', '1976-12-15')) )

all.equal(cow0., cow0x)
```

readNIPA

*Read a National Income and Product Accounts data table***Description**

Read multiple files with data in rows using `read.transpose` and combine the initial columns.

**Usage**

```
readNIPA(files, sep.footnote='/', ...)
```

**Arguments**

files	A character vector of names of files from which the data are to be read using <code>read.transpose</code> .
sep.footnote	a single character to identify footnote references in the variable names in some but not all of files.
...	optional arguments for <code>read.transpose</code>

**Details**

This is written first and foremost to facilitate updating `USFinanceIndustry` from Table 6.16: Income and employment by industry in the National Income and Product Account tables published by the Bureau of Economic Analysis of the United States Department of Commerce. As of February 2013, this table can be obtained from <https://www.bea.gov>: Under "U.S. Economic Accounts", first select "Corporate Profits" under "National". Then next to "Interactive Tables", select, "National Income and Product Accounts Tables". From there, select "Begin using the data...". Under "Section 6 - income and employment by industry", select each of the tables starting "Table 6.16". As of February 2013, there were 4 such tables available: Table 6.16A, 6.16B, 6.16C and 6.16D. Each of the last three are available in annual and quarterly summaries. The `USFinanceIndustry` data combined the first 4 rows of the 4 annual summary tables.

This is available in 4 separate files, which must be downloaded and combined using `readNIPA`. The first three of these are historical data and are rarely revised. For convenience and for testing, they are provided in the `demoFiles` subdirectory of this `Ecdat` package.

It has not been tested on other data but should work for annual data with a sufficiently similar structure.

The algorithm proceeds as follows:

1. `Data <- lapply(files, read.transpose)`
2. Is `Data` a list of numeric matrices? If no, print an error.
3. `cbind` common initial variables, averaging overlapping years, reporting percent difference
4. attributes: stats from files and overlap. Stats include the first and last year and the last revision date for each file, plus the number of years overlap with the previous file and the relative change in the common files kept between those two files.

**Value**

a `matrix` of the common variables

**Author(s)**

Spencer Graves

# Find demoFiles/*.csv
demoDir <- system.file('demoFiles', package='Ecdat')
(demoCsv <- dir(demoDir, pattern='csv$', full.names=TRUE))

nipa6.16 <- readNIPA(demoCsv)
str(nipa6.16)
```

---

recode2

*bivariate recode*

---

**Description**

Recode x1 and x2 per the lexical codes table.

**Usage**

```
recode2(x1, x2, codes)
```

**Arguments**

x1, x2           vectors of the same length assuming a discrete number of levels

codes            a 2-dimensional matrix indexed by the levels of x1 and x2. If `dimnames(codes)` are not provided, they are assumed to be `unique(x1)` (or `unique(x2)`).

**Details**

1. If `length(x1) != length(x2)`, complain.
2. `if(is.logical(x1)) l1 <- c(FALSE, TRUE) else l1 <- unique(x1)`; ditto for `x2`.
3. `If(missing(codes)) codes <- outer(unique(x1), unique(x2))`
4. `if(is.null(dim(codes))) dim(codes) <- c(length(unique(x1)), length(unique(x2)))`
5. If `is.null(rownames(codes))`, set as follows: If `nrow(codes) == length(unique(x1))`, `rownames(codes) <- unique(x1)`. Else, if `nrow(codes) = max(x1)`, set `rownames(codes) <- seq(1, max(x1))`. Else throw an error. Ditto for `colnames`, `ncol`, and `x2`.
6. `codes[x1, x2]`

**Value**

a vector of the same length as `x1` and `x2`.

**Author(s)**

Spencer Graves

**See Also**

[dim rownames link{colnames}](#)

**Examples**

```
contrib <- c(-1, 0, 0, 1)
contrib0 <- c(FALSE, FALSE, TRUE, FALSE)

  c('returned', 'received', '0', 'ERR') )

cC <- c('returned', 'returned', '0', 'received')

all.equal(contribCodes, cC)
```

---

rgrep

*Reverse grep*

---

**Description**

Find which pattern matches `x`.

**Usage**

```
rgrep(pattern, x, ignore.case = FALSE,
  perl = FALSE, value = FALSE, fixed = FALSE,
  useBytes = FALSE, invert = FALSE)
```

**Arguments**

`pattern` a [character](#) vector of regular expressions to be matched to `x`  
`x` a [character](#) string or vector for which a matching regular expression is desired.  
`ignore.case`, `perl`, `value`, `fixed`, `useBytes`, `invert`  
as for [grep](#)

**Details**

```
1. np <- length(pattern)
2. g. <- rep(NA, np)
3. for(i in seq(length=np)){ g.[i] <- (length(grep(pattern[i], x))>0) }
4. return(which(g.))
```

**Value**

an [integer](#) vector of indices of elements of `pattern` with a match in `x`.

**Author(s)**

Spencer Graves

**See Also**

[grep](#), [pmatch](#)

**Examples**

```
##
## 1. return index
##
dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
mm <- model.matrix(~ a + b, dd)

b. <- rgrep(names(dd), colnames(mm)[5])
# check

all.equal(b., 2)

##
## 2. return value
##
bv <- rgrep(names(dd), colnames(mm)[5], value=TRUE)
# check

all.equal(bv, 'b')
```

---

`sign`*Sign function with zero option*

---

**Description**

`sign` returns a vector with the signs of the corresponding elements of `x`, being 1, zero, or -1 if the number is positive, zero or negative, respectively.

This generalizes the `sign` function in the base package to allow something other than 0 as the the "sign" of 0.

**Usage**

```
sign(x, zero=0L)
```

**Arguments**

`x` a numeric vector for which signs are desired  
`zero` an `integer` value to be assigned for `x==0`.

**Value**

an `integer` vector of the same length as `x` assuming values 1, zero and -1, as discussed above.

**See Also**

`sign`

**Examples**

```
##  
## 1. default  
##  
sx <- sign((-2):2)  
  
# check  
  
all.equal(sx, base::sign((-2):2))  
  
##  
## 2. with zero = 1  
##  
s1 <- sign((-2):2, 1)  
  
# check  
  
all.equal(s1, rep(c(-1, 1), c(2,3)))
```

---

simulate.bic.glm      A "simulate" method for a BMA::bic.glm object

---

## Description

Simulate predictions for newdata for a model of class `bic.glm`.

NOTES: The `stats` package has a `simulate` method for "lm" objects which is used for `lm` and `glm` objects. This `simulate.bic.glm` function differs from the `stats::simulate` function in the same two fundamental and important ways as the `simulate.glm` function:

1. `stats::simulate` returns simulated data consistent with the model fit assuming the estimated model parameters are true and exact, i.e., ignoring the uncertainty in parameter estimation. Thus, if `family = poisson`, `stats::simulate` returns nonnegative integers. By contrast the `simulate.bic.glm` function documented here returns optionally simulated `coef` (coefficients) plus simulated values for the link and / or response but currently *NOT* pseudo-random numbers on the scale of the response.
2. The `simulate.bic.glm` function documented here also accepts an optional `newdata` argument, not accepted by `stats::simulate`. The `stats::simulate` function only returns simulated values for the cases in the training set with no possibilities for use for different sets of conditions.

## Usage

```
## S3 method for class 'bic.glm'
simulate(object, nsim = 1,
         seed = NULL, newdata=NULL,
         type = c("coef", "link", "response"), ...)
```

## Arguments

- |                      |   |
|----------------------|---|
| <code>object</code>  | an object representing a fitted model of class <code>bic.glm</code> .   |
| <code>nsim</code>    | number of response vectors to simulate. Defaults to 1.  |
| <code>seed</code>    | Argument passed as the first argument to <code>set.seed</code> if not NULL.   |
| <code>newdata</code> | optionally, a <code>data.frame</code> in which to look for variables with which to predict. If omitted, predictors used in fitting are used.  |
| <code>type</code>    | the type of simulations required. <ul style="list-style-type: none"> <li>• <code>coef type = "coef"</code> returns pseudo- random numbers generated by <code>mvtnorm::rmvnorm</code> with mean = <code>coef</code> and sigma = <code>vcov</code> for the component of the BMA mixture randomly selected for each simulation. (Obviously, this does not use <code>newdata</code>.)</li> <li>• <code>link type='link'</code> returns simulations on the scale of the linear predictors using <code>rmvnorm</code> applied to randomly selected components of the mixture with mean = <code>coef</code> and sigma = <code>vcov</code> for that component. For a default binomial model, these are of log-odds (probabilities on logit scale).</li> </ul> |

- response object[['linkinv']] of type = 'link'. For a binomial model, these are predicted probabilities.
- ... further arguments passed to or from other methods.

## Details

1. Save current seed and optionally set it using code copied from `stats::simulate.lm`.
2. `postprob <- object[['postprob']]`; `x <- object[['x']]`; `y <- object[['y']]`; `mle <- object[['mle']]`; `linkinv <- object[['linkinv']]`.
3. `cl <- as.list(object[['call']])`; `wt <- cl[['wt']]`; `fam <- cl[['glm.family']]`
4. `if(is.null(newdata))newdata <- x` else ensure that all levels of factors of `newdata` match `x`.
5. `xMat <- model.matrix(~., x)`; `newMat <- model.matrix(~., newdata)`
6. `nComponents <- length(postprob)`; `nobs <- NROW(newdata)`
7. `sims <- matrix(NA, nobs, nsim)`
8. `rmdl <- sample(1:nComponents, nsims, TRUE, postprob)`
9. `for(Comp in 1:nComponents) nsimComp <- sum(rmdl==Comp)`; `refitComp <- glm.fit(xMat[, mle[Comp,]!=0], y, wt, mle[Comp, mle[Comp,]!=0], family=fam)`; `simCoef <- mvtnorm::rmvnorm(nsimComp, coef(refitComp), vcov(refitComp))`; `sims[rmdl==Comp, ] <- tcrossprod(newMat[, mle[Comp,]!=0], simCoef)`
10. If `length(type) == 1`: return a [data.frame](#) with one column for each desired simulation, consistent with the behavior of the generic [simulate](#) applied to objects of class `lm` or `glm`. Otherwise, return a list of [data.frames](#) of the desired types.

## Value

Returns either a [data.frame](#) or a list of [data.frames](#) depending on 'type':

- |                                   |  |
|-----------------------------------|--|
| <code>coef</code>                 | a <a href="#">data.frame</a> with <code>nsim</code> columns and one row for each variable in the max model. Values are non-zero for variables in the model in the BMA mixture selected for that simulation. The non-zero values are generated using <code>mvtnorm::rmvnorm</code> with mean = <code>coef</code> and covariance matrix = <code>vcov</code> of the model fit to the subset of variables in that component model. |
| <code>link</code>                 | a <a href="#">data.frame</a> with <code>nsim</code> columns of <code>nobs</code> values each giving the simulations on the link scale for each row in <code>newdata</code> (or the training set if <code>newdata</code> is not provided).  |
| <code>response</code>             | a <a href="#">data.frame</a> with <code>nsim</code> columns of <code>nobs</code> values each giving the simulations on the response scale, being <code>linkinv</code> of the simulations on the link scale.  |
| <code>if length(type)&gt;1</code> | a list with simulations on the desired scales.   |

The value also has an attribute "seed". If argument `seed` is `NULL`, the attribute is the value of [.Random.seed](#) before the simulation started. Otherwise it is the value of the argument with a "kind" attribute with value `as.list(RNGkind())`.

NOTE: This function currently may not work with a model fit that involves a multivariate link or response.

```

## Description

Simulate predictions for newdata for a model of class `glm` with mean `coef(object)` and variance `vcov(object)`.

NOTES: The `stats` package has a `simulate` method for "lm" objects which is used for `lm` and `glm` objects. It differs from the current `simulate.glm` function in two fundamental and important ways:

1. `stats::simulate` returns simulated data consistent with the model fit assuming the estimated model parameters are true and exact, i.e., ignoring the uncertainty in parameter estimation. Thus, if `family = poisson`, `stats::simulate` returns nonnegative integers.

By contrast the `simulate.glm` function documented here returns optionally simulated `coef` (coefficients) plus simulated values for the `link` and / or response but currently *NOT* pseudo-random numbers on the scale of the response.

2. The `simulate.glm` function documented here also accepts an optional `newdata` argument, not accepted by `stats::simulate`. The `stats::simulate` function only returns simulated values for the cases in the training set with no possibilities for use for different sets of conditions.

## Usage

```
## S3 method for class 'glm'
simulate(object, nsim = 1,
         seed = NULL, newdata=NULL,
         type = c("coef", "link", "response"), ...)
```

## Arguments

<code>object</code>	an object representing a fitted model of class <code>glm</code> .
<code>nsim</code>	number of response vectors to simulate. Defaults to 1.
<code>seed</code>	Argument passed as the first argument to <code>set.seed</code> if not NULL.
<code>newdata</code>	optionally, a <code>data.frame</code> in which to look for variables with which to predict. If omitted, predictors used in fitting are used.
<code>type</code>	the type of simulations required. <ul style="list-style-type: none"> <li>• <code>coef</code> Simulated coefficients using <code>rmvnorm::rmvnorm(nsim, coef(object), vcov(object))</code>.</li> <li>• <code>link</code> The default <code>type='link'</code> is on the scale of the linear predictors using <code>rmvnorm</code> applied to randomly selected components of the mixture with <code>mean = coef</code> and <code>sigma = vcov</code> for that component. For a default binomial model, these are of log-odds (probabilities on logit scale).</li> <li>• <code>response</code> <code>object[['linkinv']]</code> of <code>type = 'link'</code>. For a binomial model, these are predicted probabilities.</li> </ul>
<code>...</code>	further arguments passed to or from other methods.

**Details**

1. Save current seed and optionally set it using code copied from `stats:::simulate.lm`.
2. `if(is.null(newdata))newdata` gets the data used in the call to `glm`.
3. `newMat <- model.matrix(~., newdata)`
4. `simCoef <- mvtnorm::rmvnorm(nsim, coef(object), vcov(object))`
5. `sims <- tcrossprod(newMat, simCoef)`
6. If `length(type) == 1`: return a `data.frame` with one column for each desired simulation, consistent with the behavior of the generic `simulate` applied to objects of class `lm` or `glm`. Otherwise, return a list of `data.frames` of the desired types.

**Value**

Returns either a `data.frame` or a list of `data.frames` depending on 'type':

<code>coef</code>	a <code>data.frame</code> with <code>nsim</code> columns giving simulated parameters generated using <code>mvtnorm::rmvnorm(nsim, coef(object), vcov(object))</code> .
<code>link</code>	a <code>data.frame</code> with <code>nsim</code> columns of <code>nobs</code> values each giving the simulations on the link scale by applying each set of simulated coefficients to <code>newdata</code> (or to the training set of <code>newdata</code> is not supplied).
<code>response</code>	a <code>data.frame</code> with <code>nsim</code> columns of <code>nobs</code> values each giving the simulations on the response scale, being <code>linkinv</code> of the simulations on the link scale.
<code>if length(type)&gt;1</code>	a list with simulations on the desired scales.

The value also has an attribute "seed". If argument `seed` is `NULL`, the attribute is the value of `.Random.seed` before the simulation started. Otherwise it is the value of the argument with a `kind` attribute with value `as.list(RNGkind())`.

NOTE: This function currently may not work with a model fit that involves a multivariate link or response.

  response=data.frame(GLMsim.r) )
attr(GLMsim2, 'seed') <- RNGstate

all.equal(GLMsio, GLMsim2)

```

**Description**

Split the first field from `x`, identified as all the characters preceding the first unquoted occurrence of `split`.

**Usage**

```
strsplit1(x, split=',', Quote='', ...)
```

**Arguments**

<code>x</code>	a character vector to be split
<code>split</code>	the split character
<code>Quote</code>	a quote character: Occurrences of <code>split</code> between pairs of <code>Quote</code> are ignored.
<code>...</code>	optional arguments for <code>grep</code>

**Details**

This function was written to help parse data from the US Department of Health and Human Services on [cyber-security breaches affecting 500 or more individuals](#). As of 2014-06-03 the csv version of these data included commas in quotes that are not sep characters. This function was written to split the fields one at a time to allow manual processing to make it easier to correct parsing errors.

Algorithm:

1. `spl1 <- regexpr(split, x, ...)`
2. `Qt1 <- regexpr(Quote, x, ...)`
3. For any (`Qt1 < spl1`), look for `Qt2 <- regexpr(Quote, substring(x, Qt1+1))`, then look for `spl1 <- regexpr(split, substring(x, Qt1+Qt2+1))`
4. `out <- list(substr(x, 1, spl1-1), substr(x, spl1+1))`

**Value**

A list of length 2: The first component of the list contains the character strings found before the first unquoted occurrence of `split`. The second component contains the character strings remaining after the characters up to the identified `split` are removed.

Spencer Graves

**See Also**

[strsplit](#) [substring](#) [grep](#)

replacement	a character to replace the substring starting and ending with characters not in standardCharacters.
gsubList	list of lists of pattern and replacement arguments to be called in succession before looking for nonStandardCharacters
...	optional arguments passed to <a href="#">strsplit</a>

### Details

1. `for(il in 1:length(gsubList)) x <- gsub(gsubList[[il]][["pattern"]], gsubList[[il]][['replacement']] x)`
2. `x <- stringi::stri_trans_general(x, "Latin-ASCII")`
3. `nx <- length(x)`
4. `x. <- strsplit(x, "", ...)`
5. `for(ix in 1:nx)` find the first and last standardCharacters in `x.[ix]` and substitute replacement for everything in between.

#### NOTES:

\*\* To find the elements of `x` that have changed, use either `subNonStandardCharacters(x) != x` or `grep(replacement, subNonStandardCharacters(x))`, where `replacement` is the replacement argument = "\_" by default.

\*\* On 13 May 2013 Jeff Newmiller at the University of California, Davis, wrote, 'I think it is a fools errand to think that you can automatically "normalize" arbitrary Unicode characters to an ASCII form that everyone will agree on.' (This was a reply on `r-help@r-project.org`, subject: "Re: [R] Matching names with non-English characters".)

\*\* On 2014-12-15 Ista Zahn suggested [stri\\_trans\\_general](#). (This was a reply on `r-help@r-project.org`, subject: "[R] Comparing Latin characters with and without accents?".)

### Value

a character vector with everything between the first and last character not in `standardCharacters` replaced by `replacement`.

### Author(s)

Spencer Graves with thanks to Jeff Newmiller, who described this as a "fool's errand", Milan Bouchet-Valat, who directed me to [iconv](#), and Ista Zahn, who suggested [stri\\_trans\\_general](#).

### See Also

[sub](#), [strsplit](#), [grepNonStandardCharacters](#), [subNonStandardNames](#) [subNonStandardNames](#) [iconv](#) in the base package does some conversion, but is not consistent across platforms, at least using R 3.1.2 on 2015-01.25. [stri\\_trans\\_general](#) seems better.

**Examples**

```
##
## 1. Consider Names = Ruben, Avila and Jose, where
##   "e" and "A" in these examples carry an accent.
##   With the default values for standardCharacters and
##   replacement, these might be converted to something
##   like Rub_n, _vila, and Jos_, with different software
##   possibly mangling the names differently. (The
##   standard checks for R packages in an English locale
##   complains about non-ASCII characters, because they
##   are not portable.)
##
nonstdNames <- c('Ra`l', 'Ra`', '`l', 'Torres, Raul',
                "Robert C. \\Bobby\\\\" , NA, '', ' ',
                '$12', '12%')

# confusion in character sets can create
# names like Names[2]
Name2 <- subNonStandardCharacters(nonstdNames)
str(Name2)

# check
Name2. <- c('Ra_l', 'Ra_', '_l', nonstdNames[4],
            'Robert C. "Bobby"', NA, '', ' ',
            '$12', '12%')
str(Name2.)

all.equal(Name2, Name2.)

##
## 2. Example from iconv
##
icx <- c("Ekstr\xf8m", "J\xf6reskog",
        "bi\xdfchen Z\xfccher")
icx2 <- subNonStandardCharacters(icx)

# check
icx. <- c('Ekstrom', 'Joreskog', 'bisschen Zurcher')

all.equal(icx2, icx.)
```

- "": Do not report any notFound elements of x.

NOTE: `x = "_"` will be identified by `attr.replacement` but not by `attr.notfound` assuming the default value for replacement.

## Details

1. `removeSecondLines`
2. `x. <- subNonStandardCharacters(x, standardCharacters, replacement, ...)`
3. Loop over all rows of `nonStandardNames` substituting anything matching `nonStandardNames[i, 1]` with `nonStandardNames[i, 2]`.
4. Eliminate leading and trailing blanks.
5. `if(is.matrix(x)) return a matrix; if(is.data.frame(x)) return a data.frame(..., stringsAsFactors=FALSE)`

NOTE: On 13 May 2013 Jeff Newmiller at the University of California, Davis, wrote, 'I think it is a fools errand to think that you can automatically "normalize" arbitrary Unicode characters to an ASCII form that everyone will agree on.' (This was a reply on `r-help@r-project.org`, subject: "Re: [R] Matching names with non-English characters".) Doubtless someone has software to do a better job of this than what this function does, but I've so far been unable to find it in R. If you know of a better solution to this problem, I'd be pleased to hear from you. Spencer Graves

## Value

a character vector with all `nonStandardCharacters` replaced first by `replacement` and then by the second column of `nonStandardNames` for any that match the first column. If a `secondLine` is found on any elements, it is returned as a `secondLine` attribute.

If any names with `nonStandardCharacters` are not found in `nonStandardNames[, 1]`, they are identified in an optional attribute per the `namesNotFound` argument.

## Author(s)

Spencer Graves

## Examples

```
##
## 1. Example
##
tstSNSN <- c('Raul', 'Ra`l', 'Torres,Raul',
            'Torres, Ra`l', "Robert C. \\Bobby\\\\" ,
            'Ed \n --Vacancy', '', ' ')

# confusion in character sets can create
# names like Names[2]
##
## 2. subNonStandardNames(vector)
```

```

##

SNS2 <- subNonStandardNames(tstSNSN)
SNS2

# check
SNS2. <- c('Raul', 'Raul', 'Torres,Raul', 'Torres, Raul',
           'Robert C. "Bobby"', 'Ed', '', '')
attr(SNS2., 'secondLine') <- c(rep(NA, 5), '--Vacancy',
                               NA, NA)

all.equal(SNS2, SNS2.)

##
## 3. subNonStandardNames(matrix)
##
tstmat <- parseName(tstSNSN, surnameFirst=TRUE)
submat <- subNonStandardNames(tstmat)

# check
SNSmat <- parseName(SNS2., surnameFirst=TRUE)

all.equal(submat, SNSmat)

##
## 4. subNonStandardNames(data.frame)
##
tstdf <- as.data.frame(tstmat)
subdf <- subNonStandardNames(tstdf)

# check
SNSdf <- as.data.frame(SNSmat, stringsAsFactors=FALSE)

all.equal(subdf, SNSdf)

##
## 5. namesNotFound
##
noSub <- subNonStandardNames('xx_x')

# check
noSub. <- 'xx_x'
attr(noSub., 'namesNotFound') <- 'xx_x'

all.equal(noSub, noSub.)

```

**Description**

Identify rows or columns of a matrix or 3-dimensional array that are all 0 and remove them.

**Usage**

```
trimImage(x, max2trim=.Machine$double.eps,
          na.rm=TRUE, returnIndices2Keep=FALSE,
          ...)
```

**Arguments**

<code>x</code>	a numeric matrix or 3-dimensional array or an object with subscripting defined so it acts like such.
<code>max2trim</code>	a single number indicating the max absolute numeric value to trim.
<code>na.rm</code>	logical: If TRUE, NAs will be ignored in determining the max absolute value for the row. If a row or column is all NA, it will be treated as all 0 in deciding whether to trim. If FALSE, any row or column containing an NA will be retained.
<code>returnIndices2Keep</code>	if TRUE, return a list with 2 integer vectors giving row and column indices to use in selecting the desired subset of <code>x</code> . This allows an array <code>y</code> to be trimmed to match <code>x</code> . If FALSE, return the desired trimmed version of <code>x</code> . If this is a list with two two integer vectors, use them to trim <code>x</code> .
<code>...</code>	Optional arguments; not currently used.

**Details**

1. Check arguments: `2 <= length(dim(x)) <= 3? is.logical(na.rm)? returnIndices2Keep = logical or list of 2 integer vectors, all the same sign, not exceeding dim(x)?`
2. `if(is.list(returnIndices2Keep))` check that `returnIndices2Keep` is a list with 2 integer vectors, all the same sign, not exceeding `dim(x)`. If yes, return `x` appropriately subsetted.
3. `if(!is.logical(returnIndices2Keep))` throw an error message.
4. Compute `indices2Keep`.
5. `If(returnIndices2Keep) return (indices2Keep) else return x appropriately subsetted.`

**Value**

`if(returnIndices2Keep==TRUE)` return a list with 2 integer vectors to use as subscripts in trimming objects like `x`.

Otherwise, return an object like `x` appropriately trimmed.

**Author(s)**

Spencer Graves

**See Also**

`trim` trims raster images, similar to `trimImage`.

`trimws` trims leading and trailing spaces from character strings and factors. Similar `trim` functions exist in other packages but without obvious, explicit consideration of factors.

**Examples**

```
##
## 1. trim a simple matrix
##
tst1 <- matrix(.Machine$double.eps, 3, 3,
  dimnames=list(letters[1:3], LETTERS[1:3]))
tst1[2,2] <- 1
tst1t <- trimImage(tst1)

# check
tst1. <- matrix(1, 1, 1,
  dimnames=list(letters[2], LETTERS[2]))

all.equal(tst1t, tst1.)

##
## 2. returnIndices2Keep
##
tst2i <- trimImage(tst1, returnIndices2Keep=TRUE)
tst2a <- trimImage(tst1, returnIndices2Keep=tst2i)

tst2i. <- list(index1=2, index2=2)

# check

all.equal(tst2i, tst2i.)

all.equal(tst2a, tst1.)

##
## 3. trim 0's only
##
tst3 <- array(0, dim=3:5)
tst3[2, 2:3, ] <- 0.5*.Machine$double.eps
tst3[3,,] <- 1

tst3t <- trimImage(tst3, 0)

# check
tst3t. <- tst3[2:3,, ]

# check
```

```

all.equal(tst3t, tst3t.)

##
## 4. trim NAs
##
tst4 <- tst1
tst4[1,1] <- NA
tst4[3,] <- NA

tst4t <- trimImage(tst4)
# tst4o == tst4
tst4o <- trimImage(tst4, na.rm=FALSE)

# check

all.equal(tst4t, tst1[2, 2, drop=FALSE])

all.equal(tst4o, tst4)

##
## 5. trim all
##
tst4a <- trimImage(tst1, 1)

tst4a. <- matrix(0,0,0,
  dimnames=list(NULL, NULL))

all.equal(tst4a, tst4a.)

```

---

truncdist

*Truncated distribution*

---

### Description

The cumulative distribution function for a truncated distribution is 0 for  $x \leq \text{truncmin}$ , 1 for  $\text{truncmax} < x$ , and in between is as follows:

$$(\text{pdist}(x, \dots) - \text{pdist}(\text{truncmin}, \dots)) / (\text{pdist}(\text{truncmax}, \dots) - \text{pdist}(\text{truncmin}, \dots))$$

The density, quantile, and random number generation functions are similarly defined from this.

**Usage**

```
dtruncdist(x, ..., dist='norm', truncmin=-Inf,
           truncmax=Inf)
ptruncdist(q, ..., dist='norm', truncmin=-Inf,
           truncmax=Inf)
qtruncdist(p, ..., dist='norm', truncmin=-Inf,
           truncmax=Inf)
rtruncdist(n, ..., dist='norm', truncmin=-Inf,
           truncmax=Inf)
```

**Arguments**

x, q	numeric vector of quantiles
p	numeric vector of probabilities
n	number of observations. If length(n) > 1, the length is taken to be the number required.
...	other arguments to be passed to the corresponding function for the indicated dist
dist	Standard R name for the family of functions for the desired distribution. By default, this is norm, so the corresponding function for dtruncdist is dnorm, the corresponding function for ptruncdist is pnorm, etc.
truncmin, truncmax	lower and upper truncation points, respectively.

**Details**

NOTE: Truncation is different from "censoring", where it's known that an observation lies between certain limits; it's just not known exactly where it lies between those limits.

By contrast, with a truncated distribution, events below truncmin and above truncmax may exist but are not observed. Thus, it's not known how many events occur outside the given range, truncmin to truncmax, if any. Given data believed to come from a truncated distribution, estimating the parameters provide a means of estimating the number of unobserved events, assuming a particular form for their distribution.

## 1. Setup

```
dots <- list(...)
```

2. For dtruncdist, return 0 for all x outside truncmin and truncmax. For all others, compute as follows:

```
dots$x <- truncmin ddist <- paste0('d', dist) pdist <- paste0('p', dist) p.min <- do.call(pdist,
dots) dots$x <- truncmax p.max <- do.call(pdist, dots) dots$x <- x dx <- do.call(ddist,
dots)
```

```
return(dx / (p.max-p.min))
```

NOTE: Adjustments must be made if 'log' appears in names(dots)

3. The computations for ptruncdist are similar.

4. The computations for qtruncdist are complementary.

5. For rtruncdist, use qtruncdist(runif(n), ...).

**Value**

dtruncdist gives the density, ptruncdist gives the distribution function, qtruncdist gives the quantile function, and rtruncdist generates random deviates.

The length of the result is determined by n for rtruncdist and is the maximum of the lengths of the numerical arguments for the other functions.

```

---

whichAeqB

*Index of a single match*

---

### Description

Return which(A %in% B) if it has length 1; give an error message otherwise.

**Usage**

```
whichAeqB(A, B, errNoMatch='no match',  
          err2Match='more than one match')
```

**Arguments**

A	A vector which may have a single match in B.
B	A vector of possible matches for A.
errNoMatch	a character string: error message if no match found.
err2Match	a character string: error message if multiple matches found.

**Value**

a single integer giving the index of the match in A.

**Author(s)**

Spencer Graves

**See Also**

[interpPairs](#)

**Examples**

```
a2b <- whichAeqB(letters, 'b')  
  
all.equal(a2b, 2)
```
